Abstract: In a variety of problems in the fields of physical sciences, engineering, economics, etc., we are led to systems of linear equations, $Ax = b$, comprising n linear equations in n unknowns $x_1, x_2, \dots, x_n$, where $A = [a_{ij}]$ is an $n \times n$ coefficient matrix, and $x = [x_1 \ x_2 \ \dots \ x_n]^T$, $b = [b_1 \ b_2 \ \dots \ b_n]^T$ are the column vectors. There are many analytical as well as numerical methods^{[1]-[11]} to solve such systems of equations, including Gauss elimination method, and its modifications namely Doolittle's method, Crout's method and Cholesky's method, which employ LU-decomposition method, where $L = [l_{ij}]$ and $U = [u_{ij}]$ are the lower and upper triangular matrices respectively. The LU-decomposition method was first introduced by the mathematician Alan M. Turing^{[2]-[11]} in 1948. Here, in this paper we have made an effort to modify the existing LU-decomposition methods to solve the above mentioned system $Ax = b$, with the least possible endeavour. It may be seen that the Gauss elimination method^{[1], [2], [3], [4]} needs about $2n^3/3$ operations, while Doolittle's and Crout's methods require n^2 operations. Accordingly, in these methods we are required to evaluate n^2 number of unknown elements of the L and U matrices. Moreover, Cholesky's method^[1] requires $2n^2/3$ operations. Accordingly this method requires evaluation of $2n^2/3$ number of unknown elements of the L and U matrices. But, in contrast, the improved Doolittle's, Crout's and Cholesky's methods presented in this paper require evaluation of only $(n-1)^2$ number of unknown elements of the L and U matrices. Moreover, an innovative method is also presented in this paper which requires evaluation of even less number of unknown elements of the L and U matrices. In this method we need to evaluate only $(n-2)^2$ number of the said unknown elements. Thus, by employing these methods, the computational time and effort required for the purpose can substantially be reduced.

Keywords: System of Equations, Matrix, Column Vector, Decomposition, Doolittle's Method, Crout's Method, Cholesky's Method

1. Introduction

There are numerous analytical and numerical methods for the solution of a linear system, $Ax = b$, including Gauss elimination method, and its modifications namely Doolittle's,

Crout's and Cholesky's methods. In the Doolittle's method LU-decomposition of an $n \times n$ matrix A is of the form $A = LU$, which is given as under,

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} & \dots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \dots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \dots & a_{3n} \\ \dots & \dots & \dots & \dots & \dots \\ a_{n1} & a_{n2} & a_{n3} & \dots & a_{nn} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & \dots & 0 \\ l_{21} & 1 & 0 & \dots & 0 \\ l_{31} & l_{32} & 1 & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots \\ l_{n1} & l_{n2} & l_{n3} & \dots & 1 \end{bmatrix} \begin{bmatrix} u_{11} & u_{12} & u_{13} & \dots & u_{1n} \\ 0 & u_{22} & u_{23} & \dots & u_{2n} \\ 0 & 0 & u_{33} & \dots & u_{3n} \\ \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & \dots & u_{nn} \end{bmatrix}$$

In the case of Crout's method this decomposition is given as,

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} & \dots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \dots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \dots & a_{3n} \\ \dots & \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots \\ a_{n1} & a_{n2} & a_{n3} & \dots & a_{nn} \end{bmatrix} = \begin{bmatrix} l_{11} & 0 & 0 & \dots & 0 \\ l_{21} & l_{22} & 0 & \dots & 0 \\ l_{31} & l_{32} & l_{33} & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots \\ l_{n1} & l_{n2} & l_{n3} & \dots & l_{nn} \end{bmatrix} \begin{bmatrix} 1 & u_{12} & u_{13} & \dots & u_{1n} \\ 0 & 1 & u_{23} & \dots & u_{2n} \\ 0 & 0 & 1 & \dots & u_{3n} \\ \dots & \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & \dots & 1 \end{bmatrix}$$

It may be mentioned that both the above quoted decompositions lead to the same solution of any linear system of equations.

For a symmetric and positive definite coefficient matrix, the LU-decomposition by the Cholesky's method is carried out as under,

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} & \dots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \dots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \dots & a_{3n} \\ \dots & \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots \\ a_{n1} & a_{n2} & a_{n3} & \dots & a_{nn} \end{bmatrix} = \begin{bmatrix} c_{11} & 0 & 0 & \dots & 0 \\ c_{21} & c_{22} & 0 & \dots & 0 \\ c_{31} & c_{32} & c_{33} & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots \\ c_{n1} & c_{n2} & c_{n3} & \dots & c_{nn} \end{bmatrix} \begin{bmatrix} c_{11} & c_{21} & c_{31} & \dots & c_{n1} \\ 0 & c_{22} & c_{32} & \dots & c_{n2} \\ 0 & 0 & c_{33} & \dots & c_{n3} \\ \dots & \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & \dots & u_{nn} \end{bmatrix}$$

The above mentioned usual LU-decomposition methods are well discussed in the books on numerical linear algebra. In these methods the coefficient matrix A is decomposed as $A = LU$, so that the linear system of equations $Ax = b$ can be written as $LUx = b$. This equation may further be written as, $Ly = b$, where, $Ux = y$. First we solve the former equation for y by forward substitution and then solve the latter for x by backward substitution. Accordingly, we obtain the solution to the given system of linear equations.

For numerical stability, pivoting is very essential unless the coefficient matrix is diagonally dominant or symmetric and positive definite. Therefore, in all the methods discussed in this paper, pivoting has been implemented before carrying out further steps.

2. Improved Doolittle's Method

The usual Doolittle's method, mentioned above, was devised by the American mathematician Myrick Hascall Doolittle (1830-1913)^{[1], [3], [7]-[12]}, which appeared in *U.S.*

$$\begin{bmatrix} 1 & a_{12} & a_{13} & \dots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \dots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \dots & a_{3n} \\ \dots & \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots \\ a_{n1} & a_{n2} & a_{n3} & \dots & a_{nn} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & \dots & 0 \\ a_{21} & 1 & 0 & \dots & 0 \\ a_{31} & l_{32} & 1 & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots \\ a_{n1} & l_{n2} & l_{n3} & \dots & 1 \end{bmatrix} \begin{bmatrix} 1 & a_{12} & a_{13} & \dots & a_{1n} \\ 0 & u_{22} & u_{23} & \dots & u_{2n} \\ 0 & 0 & u_{33} & \dots & u_{3n} \\ \dots & \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & \dots & u_{nn} \end{bmatrix}$$

Here all a_{ij} are known while l_{ij} and u_{ij} are unknown which are to be evaluated. For this purpose we multiply the right hand side matrices L and U , and equate the corresponding elements on both sides, i.e., set $a_{ij} = (lu)_{ij}$. This correspondence enables us to evaluate all the unknown elements l_{ij} and u_{ij} . Here we see that for an $n \times n$ order coefficient matrix A , it is required to evaluate only $(n-1)^2$ number of unknown elements l_{ij} , and u_{ij} of the L and U

Coast and Geodetic Survey in 1878. Here, in our improved method, we consider a linear system of n equations in n unknowns, $Ax = b$. To start with pivoting is done to ensure numerical stability. Thereafter, the system of linear equations is transcribed in such a way that the pivot equation is made to have the pivot element as unity, i.e., $a_{11} = 1$. For this purpose, if required, we may have to select the requisite equation and divide it throughout by the coefficient of x_1 for the needful, and make it the pivot equation. Following these steps, the main considerations for the decomposition of the coefficient matrix A , as $A = LU$, are as under:

- (i) The first column of the matrix $L = [l_{ij}]$ is kept the same as that of matrix A , i.e., $l_{i1} = a_{i1}$, for all i .
- (ii) The first row of the matrix $U = [u_{ij}]$ is also kept the same as that of the matrix A , i.e., $u_{1j} = a_{1j}$, for all j .
- (iii) The diagonal elements of the matrix $L = [l_{ij}]$ are kept as unity, i.e., $l_{ii} = 1$ for all i .

Accordingly, we decompose the coefficient matrix $A = LU$ as,

matrices respectively. It may be appreciated that by following the above mentioned scheme of LU-decomposition, the computational effort is substantially reduced. As described above, after having carried out the above mentioned decomposition, we solve $Ly = b$ for y , followed by solution of $Ux = y$ for x , to get the required solution to the given system of equations. Here we discuss few examples to illustrate the above mentioned method.

2.1. Solution of a System of Three Equations in Three Unknowns

We consider the following system of equations,

$$5x_1 + x_2 + 2x_3 = 19$$

$$6x_1 + 24x_2 - 12x_3 = -12$$

$$2x_1 + 3x_2 + 8x_3 = 39$$

We interchange 1st and 2nd equations and then divide the pivot equation by 6 so as to have $a_{11} = 1$, as required by the method explained above. Then we decompose the coefficient matrix as $A = LU$, according to the scheme described above. Here the coefficient matrix A is of order 3×3 , so we need to find only $(3-1)^2 = 4$ number of unknown elements of the L and U matrices, which turn out as, $l_{32} = 0.26$, $u_{22} = -19$, $u_{23} = 12$, $u_{33} = 8.84$. Thus the coefficient matrix gets decomposed as $A = LU$,

$$\begin{bmatrix} 1 & 4 & -2 \\ 5 & 1 & 2 \\ 2 & 3 & 8 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 5 & 1 & 0 \\ 2 & 0.26 & 1 \end{bmatrix} \begin{bmatrix} 1 & 4 & -2 \\ 0 & -19 & 12 \\ 0 & 0 & 8.84 \end{bmatrix}$$

Having carried out the above decomposition, we solve Ly

$$\begin{bmatrix} 1 & 2 & 3 & -4 & 1 \\ 2 & 1 & 5 & 3 & 2 \\ 3 & 4 & 1 & 2 & 4 \\ 4 & 1 & 3 & 5 & 1 \\ 2 & 4 & -1 & 2 & 5 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 2 & 1 & 0 & 0 & 0 \\ 3 & 0.67 & 1 & 0 & 0 \\ 4 & 2.33 & 0.91 & 1 & 0 \\ 2 & 0 & 0.95 & -0.34 & 1 \end{bmatrix} \times \begin{bmatrix} 1 & 2 & 3 & -4 & 1 \\ 0 & -3 & -1 & 11 & 0 \\ 0 & 0 & -7.33 & 6.67 & 1 \\ 0 & 0 & 0 & -10.73 & -3.91 \\ 0 & 0 & 0 & 0 & 0.72 \end{bmatrix}$$

After having carried out the above mentioned decomposition, we solve $Ly = b$ for y , where, $y = [y_1 \ y_2 \ y_3 \ y_4 \ y_5]^T$, and $b = [-4 \ -2 \ 4 \ 6 \ 3]^T$. Thus we obtain, $y = [-4 \ 6 \ 12 \ -2.91 \ -1.44]^T$. Thereafter, solving $Ux = y$ for x , we get the solution to the given system of equations as, $x = [1 \ 2 \ -1 \ 1 \ 2]^T$.

3. Improved Crout's Method

The standard Crout's method was formulated by the American mathematician Prescott Durand Crout (1907 – 1984)^{[6]-[12]}. As in the case of improved Doolittle's method, here also, after having carried out pivoting, the pivot equation is divided by the coefficient of x_1 . Thereafter, the

$$\begin{bmatrix} 1 & a_{12} & a_{13} & \dots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \dots & a_{2n} \\ a_{31} & a_{32} & a_{33} & \dots & a_{3n} \\ \dots & \dots & \dots & \dots & \dots \\ a_{n1} & a_{n2} & a_{n3} & \dots & a_{nn} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & \dots & 0 \\ a_{21} & l_{22} & 0 & \dots & 0 \\ a_{31} & l_{32} & l_{33} & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots \\ a_{n1} & l_{n2} & l_{n3} & \dots & l_{nn} \end{bmatrix} \begin{bmatrix} 1 & a_{12} & a_{13} & \dots & a_{1n} \\ 0 & 1 & u_{23} & \dots & u_{2n} \\ 0 & 0 & 1 & \dots & u_{3n} \\ \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & \dots & 1 \end{bmatrix}$$

Here all a_{ij} are known while l_{ij} and u_{ij} are unknown which are to be evaluated. For this purpose we multiply the right hand side matrices L and U , and equate the corresponding elements on both sides, i.e., set $a_{ij} = (lu)_{ij}$. This

= b and obtain $y = [-2 \ 29 \ 35.37]^T$. Next solving $Ux = y$ we get the solution to the given system of equations as,

$$x = [2 \ 1 \ 4]^T$$

2.2. Solution of a System of Five Equations in Five Unknowns

We consider the following system of linear equations,

$$5x_1 + 10x_2 + 15x_3 - 20x_4 + 5x_5 = -20$$

$$2x_1 + x_2 + 5x_3 + 3x_4 + 2x_5 = -2$$

$$3x_1 + 4x_2 + x_3 + 2x_4 + 4x_5 = 4$$

$$4x_1 + x_2 + 3x_3 + 5x_4 + x_5 = 6$$

$$2x_1 + 4x_2 - x_3 + 2x_4 + 5x_5 = 3$$

We divide the pivot equation by 5 in order to make $a_{11} = 1$, and then decompose the coefficient matrix as described above and obtain $(5-1)^2 = 16$ unknown elements of the L and U matrices as, $l_{32} = 0.67$, $l_{42} = 2.33$, $l_{32} = 0$, $l_{43} = 0.91$, $l_{53} = 0.95$, $l_{54} = -0.34$, and, $u_{22} = -3$, $u_{23} = -1$, $u_{24} = 11$, $u_{25} = 0$, $u_{33} = -7.33$, $u_{34} = 6.67$, $u_{35} = 1$, $u_{44} = -10.73$, $u_{45} = -3.91$, $u_{55} = 0.72$. Accordingly, we obtain,

main idea is to write out the system $Ax = b$ in such a way that the pivot equation has its pivot element $a_{11} = 1$. Furthermore, the main considerations for the decomposition of the coefficient matrix A , as $A = LU$, are as under:

(i) As in the case of improved Doolittle's method, we keep $l_{i1} = a_{i1}$, for all i .

(ii) Same as in the case of improved Doolittle's method we retain $u_{1j} = a_{1j}$, for all j .

(iii) The diagonal elements of the matrix U are kept as unity, i.e., $u_{ii} = 1$ for all i .

Accordingly, we decompose the coefficient matrix $A = LU$ as,

correspondence enables us to evaluate all the unknown elements l_{ij} and u_{ij} .

We see that for an $n \times n$ order coefficient matrix A , it is required to evaluate only $(n-1)^2$ unknown elements l_{ij} and u_{ij}

of the L and U matrices respectively. It may be appreciated that by following the above mentioned scheme of LU-decomposition, the number of operations are substantially reduced. As described above, after having carried out the above mentioned decomposition, we solve $Ly = b$ for y , followed by $Ux = y$ for x , to obtain the required solution to the given system of linear equations. Here we discuss few examples to illustrate the above mentioned method.

3.1. Solution of a System of Four Equations in Four Unknowns

We consider the following system of equations,

$$5x_1 + 10x_2 + 15x_3 - 20x_4 = -10$$

$$\begin{bmatrix} 1 & 2 & 3 & -4 \\ 2 & 1 & 5 & 3 \\ 3 & 4 & 1 & 2 \\ 4 & 1 & 3 & 5 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 \\ 2 & -3 & 0 & 0 \\ 3 & -2 & -7.33 & 0 \\ 4 & -7 & -6.67 & -10.73 \end{bmatrix} \times \begin{bmatrix} 1 & 2 & 3 & -4 \\ 0 & 1 & 0.33 & -3.67 \\ 0 & 0 & 1 & -0.91 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

Next, solving $Ly = b$, where b is the column vector, $[-2 \ 2 \ 12 \ 8]^T$ we obtain, $y = [-2 \ -2 \ -1.91 \ 1]^T$, and then solving $Ux = y$, we get the solution to above system as $x = [1 \ 2 \ -1 \ 1]^T$.

3.2. Solution of a System of Five Equations in Five Unknowns

We consider the following system of equations,

$$16x_1 - 8x_2 + 8x_3 + 16x_4 + 24x_5 = 40$$

$$3x_1 + 2x_2 + 2x_3 + 2x_4 + 4x_5 = 9$$

$$3x_1 + 3x_2 - 3x_3 + 2x_4 - 4x_5 = 7$$

$$\begin{bmatrix} 1 & -0.5 & 0.5 & 1 & 1.5 \\ 3 & 2 & 2 & 2 & 4 \\ 3 & 3 & -3 & 2 & -4 \\ 5 & -1 & -1 & 3 & -7 \\ 7 & 1 & 3 & 5 & -5 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 3 & 3.5 & 0 & 0 & 0 \\ 3 & 4.5 & -5.14 & 0 & 0 \\ 5 & 1.5 & -3.71 & -1.78 & 0 \\ 7 & 4.5 & 1.14 & 0.78 & -9.34 \end{bmatrix} \times \begin{bmatrix} 1 & -0.5 & 0.5 & 1 & 1.5 \\ 0 & 1 & 0.14 & -0.29 & -0.14 \\ 0 & 0 & 1 & 0.056 & 1.53 \\ 0 & 0 & 0 & 1 & 4.84 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

Having carried out the above mentioned decomposition, we first solve $Ly = b$, where $b = [2.5 \ 9 \ 7 \ 1 \ 5]^T$. It gives $y = [2.5 \ 0.43 \ 0.47 \ 5.84 \ 1]^T$. Next, we solve $Ux = y$, and obtain the solution to the given system of equations as, $x = [1 \ 1 \ -1 \ 1 \ 1]^T$.

4. Improved Cholesky's Method

The usual Cholesky's method for symmetric and positive

$$2x_1 + x_2 + 5x_3 + 3x_4 = 2$$

$$3x_1 + 4x_2 + x_3 + 2x_4 = 12$$

$$4x_1 + x_2 + 3x_3 + 5x_4 = 8$$

We divide the pivot equation by 5 to make $a_{11} = 1$, and then decompose the coefficient matrix, as illustrated above. Thus we obtain a total of $(n-1)^2 = (4-1)^2 = 9$ unknown elements of the L and U matrices as, $l_{22} = -3$, $l_{32} = -2$, $l_{42} = -7$, $l_{33} = -7.33$, $l_{43} = -0.33$, $l_{44} = -10.73$, $u_{23} = 0.33$, $u_{24} = -3.67$, $u_{33} = 9$, $u_{34} = -0.91$. Thus the decomposition $A = LU$, is obtained as,

$$5x_1 - x_2 - 1x_3 + 3x_4 - 7x_5 = 1$$

$$7x_1 + x_2 + 3x_3 + 5x_4 - 5x_5 = 5$$

We divide the pivot equation throughout by 16, to make $a_{11} = 1$, and then decompose the coefficient matrix as enunciated above. Thus we obtain $(n-1)^2 = (5-1)^2 = 16$ unknown terms of the L and U matrices as: $l_{22} = 3.5$, $l_{32} = 4.5$, $l_{42} = 1.5$, $l_{52} = 4.5$, $l_{33} = -5.14$, $l_{43} = 3.71$, $l_{53} = 1.14$, $l_{44} = -1.78$, $l_{54} = -0.78$, $l_{55} = -9.34$, $u_{23} = 0.14$, $u_{24} = -0.29$, $u_{34} = 0.056$, $u_{25} = -0.14$, $u_{35} = 1.53$, and, $u_{45} = 4.84$. Accordingly, we get the desired LU decomposition of the coefficient matrix as,

definite coefficient matrix was developed by French military officer, geodesist and mathematician Andre-Louis Cholesky (1876–1918)^{[1], [12]}. As discussed above, for all practical algorithms pivoting is necessary unless the matrix is diagonally dominant, or symmetric and positive definite. Here, in our improved method we follow the same scheme as in the case of improved Doolittle's method. Accordingly, we decompose the coefficient matrix $A = LU$ as,

$$\begin{bmatrix} 1 & a_{12} & a_{13} & \dots & a_{1n} \\ a_{12} & a_{22} & a_{23} & \dots & a_{2n} \\ a_{13} & a_{23} & a_{33} & \dots & a_{3n} \\ \dots & \dots & \dots & \dots & \dots \\ a_{1n} & a_{2n} & a_{3n} & \dots & a_{nn} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & \dots & 0 \\ a_{21} & 1 & 0 & \dots & 0 \\ a_{31} & c_{32} & 1 & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots \\ a_{n1} & c_{n2} & c_{n3} & \dots & 1 \end{bmatrix} \begin{bmatrix} 1 & a_{12} & a_{13} & \dots & a_{1n} \\ 0 & c_{22} & c_{23} & \dots & c_{2n} \\ 0 & 0 & c_{33} & \dots & c_{3n} \\ \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & \dots & c_{nn} \end{bmatrix}$$

Here all a_{ij} are known while c_{ij} are unknown, which are to be evaluated. For this purpose we multiply the right hand side matrices L and U, and equate the corresponding elements on both sides. This correspondence enables us to evaluate all the unknown elements c_{ij} .

We see that for an $n \times n$ order coefficient matrix A, we have to evaluate only $(n-1)^2$ unknown elements c_{ij} of the L and U matrices respectively. It may be appreciated that by following the above mentioned scheme of LU-decomposition, the number of operations are substantially reduced. As described above, after having carried out the above quoted decomposition, we solve $Ly = b$ for y , followed by $Ux = y$ for x , to obtain the required solution to the given system of linear equations. Here we discuss few examples to illustrate the above mentioned method.

$$\begin{bmatrix} 1 & -1 & 3 & 2 \\ -1 & 5 & -5 & -2 \\ 3 & -5 & 19 & 3 \\ 2 & -2 & 3 & 21 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ -1 & 1 & 0 & 0 \\ 3 & -0.5 & 1 & 0 \\ 2 & 0 & -0.33 & 1 \end{bmatrix} \times \begin{bmatrix} 1 & -1 & 3 & 2 \\ 0 & 4 & -2 & 0 \\ 0 & 0 & 9 & -3 \\ 0 & 0 & 0 & 16 \end{bmatrix}$$

Next, solving $Ly = b$, where b is the column vector, $[15 - 35 \ 94 \ 1]^T$ we obtain, $y = [15 -20 \ 39 -16]^T$, and then solving $Ux = y$, we get the solution to the given system of equations as $x = [2 -3 \ 4 -1]^T$.

4.2. Solution of a System of Five Equations in Five Unknowns

We consider the following system of equations,

$$12x_1 + 18x_2 + 24x_3 + 30x_4 + 12x_5 = 24$$

$$3x_1 - x_2 + x_3 - 2x_4 + x_5 = 9$$

$$4x_1 + x_2 + 2x_3 + x_4 - x_5 = 5$$

$$\begin{bmatrix} 1 & 1.5 & 2 & 2.5 & 1 \\ 3 & -1 & 1 & -2 & 1 \\ 4 & 1 & 2 & 1 & -1 \\ 5 & -2 & 1 & 2 & 1 \\ 2 & 1 & -1 & 1 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 3 & 1 & 0 & 0 & 0 \\ 4 & 0.91 & 1 & 0 & 0 \\ 5 & 1.73 & 0.25 & 0 & 0 \\ 2 & 0.36 & 2.19 & 0.042 & 1 \end{bmatrix} \times \begin{bmatrix} 1 & 1.5 & 2 & 2.5 & 1 \\ 0 & -5.5 & -5 & -9.5 & -2 \\ 0 & 0 & -1.45 & -0.36 & -3.18 \\ 0 & 0 & 0 & 6 & 0.25 \\ 0 & 0 & 0 & 0 & 6.68 \end{bmatrix}$$

After carrying out the above mentioned decomposition, first we solve $Ly = b$, where $b = [2 \ 9 \ 5 \ 8 -1]^T$, to get $y = [2 \ 3 -5.73 -5.75 \ 6.68]^T$. Thereafter, we solve $Ux = y$, and obtain the solution to the given system of equations as,

$$x = [1 -1 \ 2 -1 \ 1]^T.$$

5. An Innovative LU-Decomposition Method

We consider a linear system of n equations in n unknowns, $Ax = b$, where A is the coefficient matrix of order $n \times n$, while x and b are column vectors of order $n \times 1$, each. First of all we carry out pivoting unless the coefficient matrix is diagonally

4.1. Solution of a System of Four Equations in Four Unknowns

We consider the following system of equations,

$$\begin{aligned} x_1 - x_2 + 3x_3 + 2x_4 &= 15 \\ -x_1 + 5x_2 - 5x_3 - 2x_4 &= -35 \\ 3x_1 - 5x_2 + 19x_3 + 3x_4 &= 94 \\ 2x_1 - 2x_2 + 3x_3 + 21x_4 &= 1 \end{aligned}$$

Decomposing the coefficient matrix we obtain $(n-1)^2 = (4-1)^2 = 9$ unknown elements of the L and U matrices as, $l_{32} = -0.5$, $l_{42} = 0$, $l_{43} = -0.33$, $u_{22} = 4$, $u_{23} = -2$, $u_{24} = 0$, $u_{33} = 9$, $u_{34} = -3$, $u_{44} = 16$. Thus the decomposition $A = LU$, is given as,

$$5x_1 - 2x_2 + x_3 + 2x_4 + x_5 = 8$$

$$2x_1 + x_2 - x_3 + x_4 + x_5 = -1$$

We divide the pivot equation by 12 to set $a_{11} = 1$, as required by the method discussed in this paper. Thereafter, we decompose the coefficient matrix as, $A = LU$, as described above. In this case we need to evaluate $(5-1)^2 = 16$ unknown terms of the L and U matrices as, $l_{32} = 0.91$, $l_{42} = 1.73$, $l_{52} = 0.36$, $l_{43} = 0.25$, $l_{53} = 2.19$, $l_{54} = 0.042$, and $u_{22} = -5.5$, $u_{23} = -5$, $u_{24} = -9.5$, $u_{25} = -2$, $u_{33} = -1.45$, $u_{34} = -0.36$, $u_{35} = -3.18$, $u_{44} = 6$, $u_{45} = 0.25$, $u_{55} = 6.68$. This decomposition is given as,

dominant or symmetric and positive definite. This method necessitates to have the coefficients of x_1 in all the equations as unity, i.e., $a_{i1} = 1$ for all i . Any equation not fulfilling this condition may be divided throughout by the coefficient of x_1 for the needful. Thereafter, we can decompose the coefficient matrix as, $A = LU$, with the following provisions,

- (i) The first column of the lower triangular matrix $L = [l_{ij}]$ is kept the same as that of matrix A , i.e., $l_{i1} = a_{i1} = 1$, for all i .
- (ii) The first row of the upper triangular matrix $U = [u_{ij}]$ is also kept the same as that of matrix A , i.e., $u_{1j} = a_{1j}$, for $j \geq 2$. The elements of the second column of matrix L are transformed as, $l_{i2} = a_{i2} - a_{12}$,
- (iii) for $i \geq 2$.
- (iv) The diagonal elements of the matrix U are kept as

unity, i.e., $u_{ii}=1$, for all i .

(v) The remaining elements in the second row of matrix

U are transcribed as: $u_{2j} = \frac{a_{2j}-a_{1j}}{a_{22}-a_{12}}$ for $j \geq 3$.

Thus, schematically, LU-decomposition of the coefficient matrix $A = LU$, is given as under,

$$\begin{bmatrix} 1 & a_{12} & a_{13} & \dots & a_{1n} \\ 1 & a_{22} & a_{23} & \dots & a_{2n} \\ 1 & a_{32} & a_{33} & \dots & a_{3n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & a_{n2} & a_{n3} & \dots & a_{nn} \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & \dots & 0 \\ 1 & a_{22}-a_{12} & 0 & \dots & 0 \\ 1 & a_{32}-a_{12} & l_{33} & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 1 & a_{n2}-a_{12} & l_{n3} & \dots & l_{nn} \end{bmatrix} \times \begin{bmatrix} 1 & a_{12} & a_{13} & \dots & a_{1n} \\ 0 & 1 & \frac{a_{23}-a_{13}}{a_{22}-a_{12}} & \dots & \frac{a_{2n}-a_{1n}}{a_{22}-a_{12}} \\ 0 & 0 & 1 & \dots & u_{3n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & 1 \end{bmatrix}$$

After having accomplished the LU-decomposition as described above, we solve the equation $Ly = b$ for y and next solve the equation $Ux = b$ for x , to obtain the solution to the given system of linear equations. Here we consider few examples to elaborate the method discussed above.

5.1. Solution of a System of Three Equations in Three Unknowns

We consider the system of equations,

$$5x_1 + x_2 + 2x_3 = 19$$

$$x_1 + 4x_2 - 2x_3 = -2$$

$$2x_1 + 3x_2 + 8x_3 = 39.$$

We divide the first equation by 5 and the third equation by 2, throughout as required by the method elaborated above to get,

$$\begin{bmatrix} 1 & 0.2 & 0.4 \\ 1 & 4 & -2 \\ 1 & 1.5 & 8 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 3.8 \\ -2 \\ 19.5 \end{bmatrix}$$

Next, the coefficient matrix is decomposed as described above. In this decomposition only $(n-2)^2 =$

$(3-2)^2 = 1$ number of unknown, namely l_{33} is required to be evaluated which comes to 4. Accordingly, we obtain the required decomposition $A = LU$, as,

$$\begin{bmatrix} 1 & -1 & 3 & 2 \\ 1 & -5 & 5 & 2 \\ 1 & -1.67 & 6.33 & 2 \\ 1 & -1 & 1.50 & 10.50 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 1 & -4 & 0 & 0 \\ 1 & -0.67 & 3 & 0 \\ 1 & 0 & -1.5 & 8 \end{bmatrix} \times \begin{bmatrix} 1 & -1 & 3 & 2 \\ 0 & 1 & -0.5 & 0 \\ 0 & 0 & 1 & 0.33 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

After having carried out this decomposition, we solve the system $Ly = b$ for y to get $y = [15 \ -5 \ 4.33 \ 1]^T$. Thereafter, solving the system $Ux = y$, for x we obtain the solution to the given system of equations as, $x = [2 \ -3 \ 4 \ -1]^T$.

By following the method discussed above, we can solve a linear system having any number of equations with the same number of unknowns.

6. Conclusion

The solution of a system of linear equations by means of

$$\begin{bmatrix} 1 & 0.2 & 0.4 \\ 1 & 4 & -2 \\ 1 & 1.5 & 8 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 1 & 3.8 & 0 \\ 1 & 1.3 & 4 \end{bmatrix} \begin{bmatrix} 1 & 0.2 & 0.4 \\ 0 & 1 & 0.632 \\ 0 & 0 & 1 \end{bmatrix}$$

Further, solving $Ly = b$, we obtain, $y = [3.8 \ -1.3 \ 4]^T$. Thereafter, solving $Ux = y$, we get, $x = [2 \ 1 \ 4]^T$, which is the required solution to the given systems of equations.

5.2. Solution of a System of Four Equations in Four Unknowns

We consider the system of equations,

$$4x_1 - 4x_2 + 12x_3 + 8x_4 = 60$$

$$-x_1 + 5x_2 - 5x_3 - 2x_4 = -35$$

$$3x_1 - 5x_2 + 19x_3 + 3x_4 = 94$$

$$2x_1 - 2x_2 + 3x_3 + 21x_4 = 1$$

We divide the pivot equation by 4, multiply the second equation by -1 , divide the third equation by 3, and also divide the fourth equation by 2, as discussed above, and transform the given system of equations as $Ax = b$, where $b = [15 \ 35 \ 31.33 \ 0.5]^T$. Here we need to evaluate only $(n-2)^2 = (4-2)^2 = 4$ unknown number of elements of the L and U matrices, which are obtained as: $l_{33} = 3$, $l_{43} = -1.50$, $l_{44} = 8$, and $u_{34} = -0.33$. Thus we get $A = LU$ as under,

LU-decomposition of the coefficient matrix is a plausible method that can be employed analytically as well as numerically. It may be seen that for an $n \times n$ coefficient matrix, the usual Doolittle's, and Crout's methods require evaluation of a total of n^2 number of unknown elements of the L and U matrices, and in the case of usual Cholesky's method we are required to evaluate $2n^2/3$ number of unknown elements of these matrices. However, the improved Doolittle's, Crout's and Cholesky's methods need evaluation of only $(n-1)^2$ number of elements of these matrices, while the Innovative LU-Decomposition method requires evaluation of only $(n-$

$2)^2$ number of unknown elements of the L and U matrices. This difference becomes significant for systems of large number of linear equations. As such a considerable amount of computational time and energy can be saved by employing the methods presented in this paper.
