Abstract: Understanding of the effects of altitude on tree growth is central to forest management, especially in the establishment of seed source stands. A study was conducted to investigate the effect of altitude on the growth height, diameter at breast height (dbh) and volume of *Pinus oocarpa* in Malawi. Stands of *Pinus oocarpa* at the altitude of 1500m, 1700m and 1900m above the sea level (asl) were measured for total height, dbh and volume at the age of 18 years. Data obtained were subjected to analysis of variance. The results shows that there were significant ($P<0.001$) differences in total mean height, dbh and volume among the different altitudes. Higher mean height (19.2m), dbh (24.5cm) and volume (0.417m^3) was observed at 1500m asl, while total mean height, dbh and volume at 1700m asl and 1900m asl were 17.1m, 22.9cm, 0.322m^3 and 15.4m, 20.8cm, 0.243m^3 respectively. Total mean height, dbh and volume decreased with an increase of altitude. This was attributed to differences in supply of soil nutrients and specific leaf area. It is therefore, recommended that seed sources stands for *Pinus oocarpa* in Malawi and the surrounding countries should be established at 1500m to 1600m above the sea level for better genetic growth parameters.

Keywords: Total Height, Diameter at Breast Height, Volume, Specific Leaf Area

1. Introduction

Understanding of the effects of altitude on tree growth is essential for improvement of forest cover as well as central to forest management [1], especially in the establishment of seed source stands [2]. Various studies on the effect of altitude on tree growth in different species have been conducted by many researchers [1, 3 – 12]. However, mixed results have been reported. A reduction in tree height and diameter with an increase in altitude was observed in various studies [1, 3 – 5]. On the other hand, there were no significant differences in tree height and diameter growth due to different altitudes [6 – 8].

Pinus oocarpa Schiede ex Schltdl. is one of the major exotic plantation species in Malawi and other Southern African countries. This species of pine tree is native to Mexico and Central America [13]. It is a national tree of Honduras, where it is known as Ocote [14]. Trees of *Pinus oocarpa* can be recognized by their irregular crowns, thick, gray, platy bark, ovoid-shaped cones with a large thick peduncles, and needles in fascicles of five. The tree species occurs from 350 to 2500 m above the sea level in Mexico and Central America but

reaches its best development between 1200 and 1800 m above the sea level where the soils are deep and annual rainfall are above 1200mm. The growth rates in these regions are approximately 3 to 4 m^3 per hectare per year [15]. Tree size varies considerably over its range; heights up to 37 m; diameters 40 to 80 cm and occasionally 127 cm. Boles are cylindrical, straight and clear up to 15 m or more and it is fire resistant [16]. Nevertheless, the tree grows poorly and reach the height of 10 to 15 m in northern Mexico, where the climate is drier than in most parts of Central America. Trees are also often less than 10 to 12 m height where they grow at elevations below 800 to 900 m above the sea level or on shallow, eroded soil on ridge tops. The growth rate in these dry regions is approximately 1 m^3 per ha per year [15]. *Pinus oocarpa* has a seed potential of about 140 seeds per cone. The number of seeds per kg varies from 43000 to 78000 and in Guatemala the seed size was found to decrease with increasing elevation [15, 16]. In contrast, seed yields are poor for *Pinus oocarpa* planted as exotic near the equator but improve with increasing latitude [15]. For example, Arce and Isaza [17], as reported by [15],

found only seven filled seeds per cone in stands established between 1360 m and 1800 m above the sea level of 12 to 21 years of age in Columbia (2° N latitude), while about 25 filled seeds per cone were found in Venezuela (10° to 11°N latitude) in stands 10 to 12 years of age when established above 800 m above the sea level. Seeds of *Pinus oocarpa* usually will begin to germinate in 7 to 10 days using standard nursery or laboratory techniques. Seedlings reach a planting height of 20 to 25 cm in 5 to 7 months [15]. *Pinus oocarpa* is an important timber tree. The wood is easy to work with hand and machine tools. In Mexico and Central America, the wood is used for plywood, construction lumber, packing boxes, fuel wood, kindling as well as resin production [14].

The tree species was introduced in Malawi in 1950's for timber and it is now grown in most parts of the country at different altitudes. There is a general agreement in literature that growth of *Pinus oocarpa* varies according to location [14, 15]. Despite this, no information is available on the growth performance of *Pinus oocarpa* at different altitudes in Malawi. Therefore, the purpose of this study was to investigate the influence of altitude on the growth performance of *Pinus oocarpa* in Malawi. The information on growth performance of *Pinus oocarpa* at different altitude would be incorporated into decision support system in Malawi to assist the forestry industry in planning and establishment of best seed sources sites with high genetic growth parameters.

2. Methods

2.1. Study Site

This study was conducted in Malawi near the tropical savannah region in Southern Africa at Dedza Mountain Forest Plantation (Figure 1). Dedza Mountain lies on latitude 14°20'S and longitude 34°20'E and it rises up to about 2200m above the sea level. It receives 1200 mm to 1800 mm rainfall per annum, with annual temperature ranging from 7 °C to 25 °C (Figure 2). The soils are high in ferralsols, acrisols and nitosols. It is situated about 85 km southeast of Lilongwe, the capital.

2.2. Forest Stands, Plots and Data Collection

Seedlings of *Pinus oocarpa* at the age of six month after pricking out were planted on nine compartments of 1.2 ha each at three different altitudes (1500m, 1700m, and 1900m above the sea level) in 1994. Each altitude had three compartments, totalling to 10.8 ha area planted. The mean height and root collar diameter of the seedlings were 26.8 cm and 5.1mm respectively. Hole planting was done at a spacing of 2.75m x 2.75m (1320 stems ha⁻¹) in all the compartments. Low thinning was carried out at the age of 9 and 15 years by removing 35% and 28% of the trees respectively. At the ages of 4, 9 and 15 years pruning was carried out in all the compartments. Trees were pruned to half of the stem height.

At the age of 18 years, 250 trees per compartment were systematically selected and measured for total height, diameter breast height (dbh) (1.3m above the ground) and

volume. Suunto clinometer and calliper were used to measured total height and dbh respectively, while tree volume was calculated from the tree diameter and height using a tree volume function [18]. The longest fresh needle found on ground for the measured trees were also measured by a 30 cm ruler. Eight circular sample plots of 0.05 ha each were systematically constructed in each compartment and total number of trees were counted. This was done in order to determine the stocking per hectare for each altitude so that the natural mortality rate at each altitude is known. The stocking per hectare and natural mortality rate was calculated using formula's as expressed by [18]. Prior to tree measurement soil analysis was done. Site characteristics information is presented in Table 1.

Table 1. Site description.

Altitude (m asl)	1500	1700	1900
Longitude;	34°20'E;	34°19'E;	34°19'E;
Latitude	14°22'S	14°22'S	14°21'S
Slope (%)	6	10	10
Aspect	East	East	East
Soil pH(H ₂ O)	6.4	6.3	6.3
P (mg kg ⁻¹)	14.7	10.6	6.50
Zn (mg kg ⁻¹)	0.59	0.48	0.41
Fe (mg kg ⁻¹)	5.77	5.71	5.62
Mn (mg kg ⁻¹)	5.98	5.73	5.46

2.3. Statistical Analysis

Data obtained were tested for normality and homogeneity with Kolmogorov-Smirnov D and normal probability plot tests using Statistical Analysis of Systems software version 9.1.3 [19]. After the two criteria were met the data were subjected to analysis of variance (ANOVA) using the same Statistical Analysis of Systems software and means were separated with Fischer's least significant difference (LSD) at the 0.05 level.

3. Results and Discussion

Mean height, dbh and volume growth are presented in Table 2. The results shows that there were significant ($P<0.001$) differences in mean height, dbh and volume of *Pinus oocarpa* among the altitudes. The altitude of 1500 m above the sea level had higher values of mean height, dbh and volume than the altitudes of 1700m and 1900m above the sea level. Mean height, dbh and volume decreased with an increase in altitude. However, diameter increment declined less, 6.5% and 15% from 1500m to 1700m and from 1500m to 1900, with increasing elevation than height, 11% and 20% respectively. There was a similar trend for dbh growth and volume growth. The reason behind this is that dbh is highly positively correlated with volume [20].

The present results are in agreement to those in literature [1, 3-5, 9-12]. Growth rates may decline with increased altitude due to reduced air and soil temperature (an adiabatic effect), increased exposure to wind, and reduced supply of nutrients [4]. This may be true for the present study since nutrients decreased with an increase of altitude (Table 1). Coomes and Allen [4] reported that phosphorus availability is known to

decline with an increasing altitude and this may contribute to the slow growth at high altitudes. On the other hand, [6-8] did not find a statistically significant effect of change in altitude on

tree diameter. These differences may be attributed to the fact that various site factors influence diameter growth [12].

Figure 2. Weather for the study area

Table 2. Mean height, diameter at breast height (dbh) and volume of *Pinus oocarpa* at the age of 18 years for different altitudes.

Altitude (m asl)	Height (m)	dbh (cm)	Volume (m ³)
1900	15.4±0.6 ^c	20.8±0.2 ^c	0.243±0.005 ^c
1700	17.1±0.5 ^b	22.9±0.2 ^b	0.322±0.004 ^b
1500	19.2±0.5 ^a	24.5±0.3 ^a	0.417±0.005 ^a
CV (%)	7.9	6.3	19.6

Note: ^{a,b,c} means with different subscript within a column significantly differ ($P<0.001$)

Table 3 shows that there were significant ($P<0.001$) differences in estimated stocking per hectare among the different altitudes and these lead to the significant differences in natural mortality rate per year among the different altitudes. Natural mortality rate increased with an increase in altitude. Looking at this one would expect that trees grown at 1900 m above the sea level would have higher values of mean height and dbh than those grown at 1700m and 1500 m above the sea level. This is so because trees grown at 1900 m above the sea level have more space, hence the competition for light is less, which could result in high rate of photosynthesis than those grown at 1700m and 1500m above the sea level. However, the results were opposite. This was attributed to the length of the needles. The length of needles decreased with an

increase of altitude (Table 3). The present results are in agreement to those in literature [21, 22]. Grace [21] reported that morphological characteristics of needles change with altitude, thus at higher altitudes needles were shorter as a result they demonstrated a lower specific leaf area. This implies a diminished importance of any trend towards increased surface conductances, hence low rate of photosynthesis.

The length of needles at higher altitudes decreases as a result of an increase in wind [21]. As wind increases with an increase in altitude, a rapid increase in damage to leaves (needles) caused by mutual abrasions of the plants parts and blown soil particles is also expected [23], such damage may not only increase transpiration, but it may disrupt the turgor relations of the epidermis and thus prevent proper stomatal closure [22]. Therefore, the decrease in length of needles is attributed to stomatal dysfunction caused by mechanical damage to the leaf and also by damage to the epidermis [21]. The present study has shown that the growth of *Pinus oocarpa* decreases with an increase in altitude. It is therefore, recommended that seed sources stands for *Pinus oocarpa* in Malawi and the surrounding region should be established at 1500m to 1600m above the sea level for better genetic growth parameters.

Table 3. Expected and estimated stocking per hectare, natural mortality rate per year and mean needle length for *Pinus oocarpa* at different altitudes.

Altitude (m asl)	Expected stocking (stems ha ⁻¹)	Estimated stocking (stems ha ⁻¹)	Natural mortality rate per year (%)	Mean Needle length (cm)
1900	620±3	559±4 ^c	0.55±0.02 ^c	15.4±0.8 ^c
1700	620±3	572±3 ^b	0.43±0.01 ^b	18.7±0.6 ^b
1500	620±3	598±4 ^a	0.20±0.02 ^a	21.2±0.9 ^a
CV (%)		8.2	8.1	5.3

Note: ^{a,b,c} means with different subscript within a column significantly differ ($P<0.001$)

4. Conclusion

The present study has revealed that altitude has a clear effect on growth height, diameter at breast height and volume of *Pinus oocarpa*. Total height, dbh and volume decreases with an increase in altitude. It is therefore, recommended that seed sources stands for *Pinus oocarpa* in Malawi and the surrounding region should be established at 1500m to 1600m above the sea level for better genetic growth parameters.
