Awal, Mohd Abdul. Analysis of Environmental Degradation in Natural Resources. *American Journal of Applied Chemistry*. Vol. 2, No. 5, 2014, pp. 63-73. doi: 10.11648/j.ajac.20140205.11

Abstract: For centuries the area which is now Bangladesh was known throughout the civilized world for its fabled wealth, of which the exquisite muslin, Sundarbans, Cox's Bazar un-broken sea beaches were the apt symbol. Aryans, Turks, Mughals, Afghans, Arabs, Dutch, Portuguese, French and British were attracted by the opulence of Bengal. They came as invaders, traders, settlers, missionaries and in their different ways, contributed towards making this country a distinctive entity among the world's nations, boasting numerous historical and natural assets. However, this is kaleidoscopic presentation of our land called coastal belt in Bangladesh, its valiant people imbued with a sense of history, its rich and flora and fauna, its verdant landscape with lush green fields, enchanting hills and hillocks and the meandering rivers falling into the vast blue expanse of the Bay of Bengal. It is a land of enormous economic potentials, inhabited by diligent and hard-working people who have a love for heritage. It is a land of ancient and variegated religious and cultural traditions. All of these together make Sundarbans a colorful mosaic of nature's splendor and bounty (Awal, 2014). Despite various hypotheses as to the causes of this natural degradation, the underlying causes are still not well understood. The present work has explored some of the possible factors involved, focusing particularly on the relationship among the environmental factors and the human destruction of Sundarbans ecosystem as well as abnormal concentrations of a number of chemical elements present in the soil, in order to test the hypothesis that ecological pollution, along with chemical pollution might be responsible. However, the present results have showed that Sn, Exchangeable K, soil pH, Pb, Zn and Ni could be directly linked with top-dying disease of *Heritiera fomes* (Sundri) in Sundarbans, probably particularly by weakening the vigor of the trees and people and allowing other factors such as pathological agents to attack the plants and surrounding people in Sundarbans, Bangladesh (Awal, 2014). In fact, from since then and still now, the natural resource of Bangladesh like Sundarbans is being disturbed ecologically by human destruction.

Keywords: Causal Factors, Heavy Metal Concentrations, Pollution, *Natural Resources Degradations*, Sundarbans, Chemical Contamination, Top-Dying, Disease of Plants & Surrounding People

1. Introduction

Bangladesh is literally a treasure-trove of rich and variegated natural beauty interspersed with enchanting landscape, mighty meandering rivers, exotic flora and fauna, picturesque resorts, long sunny beaches, tropical mangrove forests, fascinating art and architecture, ancient relics and archaeological sites and colorful tribal life. As a vacation land, Bangladesh has many facets. Bangladesh has considerable resources to augment its economic growth for providing a better to its people. History records that till the advent of the British in the eighteenth century; Bangladesh had an enviable position in the entire region and was known as the legendary land of affluence and prosperity. The country has almost achieved green revolution. Sub-sectors like fishery, livestock rearing, and forestry are growing by

leaps and bounds. The Bay of Bengal is literally a treasure-trove of sea fish and other wealth. Bangladesh's major natural resource is gas. There is also bright prospect of striking oil. Huge deposits of coal, limestone, peat, bitumen, hard rock, lignite's, white clay etc. have already been indentified and projects are being implemented for their harnessing for productive use (Mosaic of Bangladesh; 2006; External Publicity Wing; Ministry of Foreign Affairs; Government of the People's Republic of Bangladesh; p:1-145).

1.1. The Sundarbans

The Sundarbans, a World Heritage site, is composed of three wildlife sanctuaries, namely the Sundarbans East Wildlife Sanctuary, Sundarbans South Wildlife Sanctuary and Sundarban West Wildlife Sanctuary. The total area of the

World Heritage Site is 1400 sq. km. out of which 910 km is land area and 490 km is water. A complex network of tidal waterways, mudflats and small islands with salt-tolerant mangrove forest, make up the three sanctuaries. The area has been recognized globally for its importance as a reservoir of biodiversity. The mangrove supports a unique assemblage of flora and fauna, including charismatic mega fauna like the Royal Bengal Tiger., the estuarine crocodile and the Ganges river dolphin or Susuk. The Sundri tree, after which the Sundarbans is named, is native to the forest. A visit to Bangladesh would remain incomplete if the Sundarbans appear in the itinerary. It is situated in the southwest corner of Bangladesh. It is the largest mangrove forest in the world, criss-crossed by creeks and canals creeping around thousand of islets that swell and sink with the tide in the Bay. The cluster of isles, the water bodies and mangrove together support an eco-system at once unique with the result that Sundarbans could be easily developed into a treasure house of biodiversity. It is home to 80% of reptiles, 40% of mammals' species and about 50% of all bird species found in Bangladesh. Of the 35 mangrove plant-species spotted in the whole world, 14 are found in the Sundarbans. The total area of the Sundarbans is 5772.85 sq km. The forest occupies 4016.85 sq km of land while rivers, canals and channels occupy 1756 sq. km. The mangrove forest in the Sundarbans, particularly in the three wildlife sanctuaries, acts as a good nursery and potential breeding ground for shrimps, prawns and many other edible fishes. For its outstanding natural value, the World Heritage Committee of UNESCO inscribed the Sundarbans of Bangladesh in the World Heritage list in their 21st session in 1997 and accordingly the Government of the People's Republic of Bangladesh declared the Sundarbans as a World Heritage Site in 1999. The attractions of this forest are varied and many. Wild, unspoiled and unpolluted beaches are scattered here and there along the borderline of the Bay. The flora of the Sundarbans includes *Sundri*, *Keora*, *Gewa*, *Golpata*, *Goran* and *Passur*. The fauna can boast the legendary Royal Bengal Tiger, spotted deer, dolphin etc. Of the reptile species there are the estuarine crocodiles, pythons, lizards, flap-shelled spotted turtles and green turtles. The fish population has *betki*, *rekha*, *boncha*, *faissa*, *pangash*, *ritha*, *silon*, *hilsha*, *catfish*, *lobster*, *shrimp*, *prawn* etc. The forest is bird watchers' paradise as it is the abode of varieties of rare and colorful birds like the pond heron, green pond heron, kingfisher, cattle egret, little egret, golden plover, white-backed vulture, fishing eagle, white-breasted eagle, clustered-surpented-eagle, white-caped-eagle, red-jungle-fowl and so on. The noteworthy beauty spots of the Sundarbans are Katka, Kachikhali, Herion point or NilKamal, Manderbaria, Karamjal, Dublar Char, Narikel-Baria Char etc.

1.2. Severity of Destruction in Sundarbans Natural Resources

Bangladesh is the one of the most densely populated countries, and it has about 147.37 million people (World Fact book, July 2006) in an area of 144,000 sq Km (World Fact

book, July 2006). Bangladesh is facing many problems including environmental pollution, high population density and poverty, these problems being interlinked with each other. These unique coastal tropical forests are among the most threatened habitats in the world. They may be disappearing more quickly than inland tropical rainforests, and so far, with little public notice. The Sundarbans provide critical habitat for a diverse marine and terrestrial flora and fauna, and 3.5 million people depend on Sundarbans forests and waterways for their survival (Anon, 1986; Chaffey *et al*, 1985). Enrichment and illicit removal of timber and firewood from the forests are the major forest conservation problems in Sundarbans. Approximately 2.5 million people live in small villages surrounding the Sundarbans, while number of people within 20 km of the Sundarban boundary was 3.14 million (Islam, 1993). The total forest area of Bangladesh is about 2.47 million ha, which accounts for about 18% of the total land area of the country, and which constitutes 0.15% of the world's total tropical forests (Haque, 2000), although an estimate from 1993 only put the tree cover at 5-7% of the country's area (FAO,1993). Sundarbans comprises 45% of the total productive forests in Bangladesh, and contributes about 50% of forest related revenue. The 1993 total wood supply in the country was 6.2 million m³ against a demand of 8.34 million m³, with a sustainable local supply for only 1.3 million m³. Sixty five percent of forest products are consumed as fuel wood (GOB, 1993). The annual average destruction of forest land in the country was 8000 ha in 1980 and subsequently it increased to 38000 ha in 1981-90 according to FAO (1993). But probably the rate of destruction of forest is more severe than the official statistics as it is very difficult to estimate the real picture. Deforestation affects one eighth of the country's land areas. The Bangladesh government has now officially banned the felling, realizing that the forest had degraded due to excessive felling.

Possibly, many factors contributed to loss of Sundarbans, including the charcoal and timber industries, but also urban growth pressures and mounting population pressure and environmental-pollution. The significant and recent causes of Sundarbans mangrove loss in the past decade have included the customer demands for luxury shrimp, or "prawns", and the destructive production methods of export-oriented industrial shrimp farms and factories (Personal observation, 1994-97). The failure of governments to adequately regulate the shrimp industry, and the headlong rush of multilateral lending agencies to fund aquaculture development without meeting their own stated ecological and social criteria have all played a part (Personal observation, 1995-1998).

Approximately 100,000 to 200,000 people work inside the Sundarbans for at least 6 months, while the number of people entering the forest in a year could be as high as 3,000,000 (Hussain and Karim, 1994). Of these, about 25,000 people work in fish drying and 60,000 – 90,000 people in shrimp post-larvae collection inside the Sundarbans (FAO, 1994). About one million people are engaged in shrimp larval collection in the rivers and creeks around the outside of the

Sundarbans (Chantarasri, 1994).

Sundarbans supports potential fishery resources and constitutes an important commercial and artisanal fishery industry that produces fresh fish, iced fish, sun dried fish, and smoked fish, salted fish, fish meal and sharks oil (Figure 1.0). Thus, Sundarbans provides a considerable harvest of whitefish, shrimps, prawns, mud crabs, snails / oysters and billions of shrimps, prawns, and post larvae for shrimp aquaculture farms. These industries support about 155,000 fishermen throughout the year, and economic valuation of the fisheries function of mangroves was estimated to range from US\$ 66 to almost 3,000 per ha (Hambrey, 1999).

Sundarbans also supports the livelihood and earnings for about two million people of the adjoining areas at least part of the year i.e. during the winter season for fishing, collection of *Nypa* leaf and Goran fuel wood (Hussain and Karim, 1994). The local *Apis dorsata* has a big commercial importance. Traditional honey hunting is an interesting item for the tourists operated from April to July each year. About 30,000 kg of honey and 80,000 kg of raw wax are harvested annually (Islam, 1993). These products are widely used in the pharmaceutical industries. According to Guha (1989), historically there has been the transformation of resource utilization patterns by both the relevant government departments and traditional users. Paramount among these changes were shifting from communal to individualized forms of use, as encouraged by the permit system and by leasing rights and employment practices introduced by the Forest Department. The state policy towards the Sundarbans began in the 1770s. In 1785, Tilman Henckell, the judge-magistrate in Jessore, gave out 150 leases and established three market towns in the area. The Sundarbans always belonged to the state and did not come under the purview of the Permanent Settlement Act of 1790; Zamindars or landlords were not to collect revenues or taxes from the Sundarbans. In 1862, Dr. Brandis, the Conservator of Forests in Burma, put up a convincing argument in favor of preserving the Sundarbans (Banerjee, 1964). Additional reclamation grants were stopped, but forest was leased to the port Canning Company. This was a company newly formed to build a replacement to the port of Calcutta, which was considered to be dying because of the silting up of the Hooghly River.

Figure 1.0. Photograph of part of the Sundarbans coastal area, near compartment number 26, where the trees have been cut down to be replaced by a fishing village.

However, the lease was cancelled in 1868 because of the Company's oppressive behavior toward the traditional users of the forest (Banerjee, 1964). On December 7, 1878, Dr. Brandis' intercession became effective, and portions of the Sundarbans were declared "reserved" and "protected" (Mukherjee, 1975).

The Sundarbans, like other tidal forests, is tolerant of natural disturbances such as the cyclones and tidal waves of the Bay of Bangle, but it is highly vulnerable to human disturbances (Seidensticker, 1983). Most of the abuses found in professional forestry management elsewhere have been observed here as well, such as excessive cutting of stocks in the auctioned area and connivance between purchasers and forestry staff to cut wider areas than sanctioned (Bari, 1993). The major usable forest species include a wide variety of mangroves, and government auction of trees such as the gewa, sundri, and nipa palm have brought substantial revenues each year (Bari, 1993). Gewa is the principal supply of raw-material for the Khulna Newsprint Mills, a 48,000-ton facility built in 1959, and a significant (GRPB, 1985) export earner. Much, if not most, of this industry was situated to the east of Sundarbans, but there appeared to be considerable interest in increasing crustacean culture in the reserved forest (GRPB, 1985), an interest doubtless spurred by the Government target for exporting shrimp included in the 1985-90 five-year-Plan (GRPB, 1985).

Another factor is a long-term ecological change which is taking place in the Sundarbans due to the eastward migration of the Ganges, abandonment of some tributaries, diversion of water and withdrawals for irrigation. Up to 40% of the dry season flow of the Ganges has been diverted upstream, following the completion of the Farraka Barrage in India in 1974. Decreased fresh-water flushing of the Sundarbans results in increased saline intrusion, particularly in the dry season. Concern has been expressed about recent indications of apparent deterioration in the flora, including localised die-back of Sundri, commercially the most valuable tree species, which might be associated with the decrease in freshwater flow, either as a direct effect of increasing salinity or other associated edaphic changes. A gradual replacement of *Heritiera fomes* with *Excoecaria agallocha*, therefore, is a likely long term effect (Christensen, 1984), and certainly deterioration in the vegetation is already well-documented (International Engineering Company, 1980). Besides recent changes in vegetation, geomorphic changes in the Sundarbans environment are also rapid (Personal observation; Faizuddin, 2003). Also, there were 157 major oil spills in tropical seas between 1974 and 1990 (Burns *et al.*, 1993). Deep mud coastal habitats may take 20 years or more to recover from the toxic effects of such oil spills (Phillips, 1994). Some more details on specific threats to the Sundarbans are given in the following sections. It should also be remembered that these factors probably do not only operate singly, but are likely to interact in their effects; however, they have been divided into individual factors for convenience of discussion.

2. Methodology

In this section the various field and laboratory methods used in this study will be discussed as below:

2.1. Field Sampling Methods

The Sundarbans Reserved Forest is located at the south west corner of the Ganges River Delta close to the Bay of Bengal, mainly on the sea-shore line, river banks, channels, and small creeks. The location of the Sundarbans within Bangladesh has been shown in *Figure 2.0*.

2.1.1. Site Selection and Location of the Study Area

General reconnaissance of possible sites was made by visiting all the possible regional areas before categorizing and selecting plots for sampling. It was decided to sample from the Chandpai area which is the mostly human accessible and ecologically polluted area (in *Figure 1.0*). Three compartments from this regional area (range), namely numbers 26, 28 and 31, were selected because they were believed to represent a range of severity of top-dying disease, based on relevant maps, documents, literature, consultations with forest professionals, and surrounding peoples. The location of these compartments within the Chandpai area, and the location of this area in the wider Sundarbans is shown in *Figure 2.0*. Among the three compartments, compartment number 26 was selected as an area highly affected by top-dying, where most of the trees were affected severely. Compartment 26 had pronounced human activities, and also in places is undergoing rapid housing development involving extensive construction activities due to the presence nearby of the Range HQ office in Chandpai (in *figure 1.0*). Compartment number 28 was selected as a moderately affected area. This compartment has various human activities including boat making grounds, football-playing grounds, and cattle-grazing fields, all types of major soil erosion, a moderate amount of construction activities and the presence of communities of fishermen (*figure 1.0*). Compartment number 31 was chosen as being relatively little affected by top-dying disease.

Of the three chosen compartments, the nearest compartment to Mongla port is compartment 31, with comparatively modest human activities, but which nonetheless involve clear-cutting of natural vegetation, replanting with other species rather than mangrove or other native species, all types of soil erosion, and construction activities present. Within each of the three compartments, detailed observations of the regeneration and sampling of soil and water took place within three 20 m x 20 m plots, chosen to reflect a range of top-dying intensities (High, medium and

Low for that area). The sampling was conducted in a randomized block design, in that a plot was sited within a particular top-dying intensity block, but the precise location of that plot was randomized so as not to bias the detailed data collection. Thus in total nine plots were sampled, representing a range of top-dying intensities.

Intensive field data collection was made among these nine selected plots (in *Figure 3.0*). Observations were performed from observation towers during low and high tides, also traversing the forest floor and vegetation on foot, as well as using a speed boat, trawlers, country-boats, and a launch as required to gain access.

Figure 3.0. Photograph showing the Sundarbans forest trees and understory vegetation. The adult trees behind the author are of *Heritiera fomes*. The forest floor shows dead leaves from trees affected by top-dying.

Figure 2.0. Map showing the location of the numbered compartments within the Chandpai area, and the position of this area relative to other parts of the Sundarbans in Bangladesh (darker shaded area).

Table 1.0. Data on locations of plots, as indicated by Geographical Position System (G.P.S).

Compartment. Number.	Plot Number.	Global Position Systems (GPS) reading.	
		North latitudes	East longitudes
26	1	N 22° 32'.35	E 089° 64'.47
26	2	N22° 32'.98	E089° 64'.28
26	3	N 22° 33'.82	E 089° 63'.50
28	4	N 22° 36'.73	E 089° 66'.53
28	5	N 22° 36'.38	E 089° 66'.91
28	6	N 22° 36'.89	E 089° 66'.29
31	7	N 22° 42'.82	E 089° 57'.61
31	8	N 22° 42'.72	E 089°58'.44
31	9	N 22° 44'.20	E 089° 58'.21

All sampling was accompanied by Deputy Rangers, Foresters, and Forest guards armed with a rifle from the local office, Chandpai range, Bangladesh Forest Department, to prevent a fatal attack by a Bengal tiger (*Panthera tigris*).

Fieldwork was performed in October, 2003 to March, 2004. Locations of sampling points were determined using a Global Positioning System with a precision of 5-10 m (Table 1.0). For one typical plot, in compartment 31, the altitude was recorded as 4.4 m above sea level.

2.1.2. Vegetation Recording Methods in the Field

Within each of the nine 20mx20m plots, each adult tree was assessed for three parameters. The diameter at 1 m height was recorded (in cm) by using a tree diameter-measuring tape or slide callipers depending on girth. The tree height to the top of the crown was determined mainly by ocular estimation but some heights were checked by using Clinometers at a set

distance of 20 m to test the accuracy of such ocular estimations.

Finally, the status of the tree in respect of the amount of top-dying was assessed by using a four point qualitative scale of intensity, namely; not affected, little affected, moderately affected or highly affected by top-dying. This was later expressed as a semi-quantitative or rank scale of 0 to 3 respectively, so that a median rank value could be calculated and used as an index of top-dying intensity in that plot. After that, the total number of seedlings (individuals of the tree species <1 m tall), and saplings (young trees >1 m tall with a diameter of trunk of < 10 cm), were counted within the plots. Care was taken to ensure that trees, saplings and seedlings were not counted more than once or missed in the counting process. After recording, adult trees were marked with white chalk to segregate those marked trees from other trees, seedlings and saplings; red paints were applied to all seedlings and saplings as they were recorded.

2.1.3. Soil and Water Sampling Methods

As stated above, from the three selected compartments, a total of nine plots of 20m x 20m were selected. From each of these plots, seven soil samples were collected; one from the centre of the plot, four (one each) from all the corners, and two from the middle sides of the plot. Therefore a total of 63 soil samples were taken. Also nine water samples were collected from nearby rivers, creeks or channels, one from the area of each of the sampled plots. Soil samples were collected from 0-30 cm soil depth by using a stainless steel spatula and steel cylinder ($d=5.25$ cm), and all soil samples were kept in sealed plastic bags. Water samples were collected directly in pre-cleaned plastic-containers. Marking and labelling was performed with a detailed description of the selected sampling site on both the soil-containing plastic bags and water containers, and preserved in portable coolers until arrival at the laboratory at Dhaka University for initial chemical analysis. This field sampling method followed the W.H.O, U.K, and E.P.A systems of standard laboratory and field sampling principles, rules and regulations. Rainfall for the area during sample collection was not notably different from the respective monthly averages for the Sundarbans of recent years (shown in Table 2.0 for reference); there was no heavy intensity of rainfall within one month before sampling.

Table 2.0. Showing previous monthly average rainfall data.

Year	1996	1997	1998	1999	2000	2002
Location	Mongla (mm)	Mongla (mm)	Mongla (mm)	Mongla (mm)	Mongla (mm)	Mongla (mm)

November	1	4	207	12	5	89
December	25	13	0	0	0	0

Any evidence of changes was recorded, sometimes obtained through asking local people and forestry staff, or from personal observations. In particular, any soil erosion and diversion of the river's position or of new channels and creeks observed during the data collection period were recorded, as were signs of siltation changes.

2.1.4. Questionnaire Survey of Local People

In order to establish the views of local people about the incidence and causes of top-dying, a questionnaire was prepared for asking peoples either individually or in groups. This survey was done among people living or working in the 17 Sub-Districts of Sundarbans, making a distinction between those living within and outside of Sundarbans. They were asked whether they had seen the top-dying disease of *Heritiera fomes* (Sundri) in Sundarbans for a long time, either through living within the Sundarbans or through visiting Sundarbans for their daily work, for their professional work such as forestry officials, for fishing or for collecting wood as wood cutters, for seasonal honey collection, or other purposes. Groups were made up among targeted people in all locations and from all categories mentioned above, based on age, profession, and also for their sharp memory. In this way, 50 questionnaires were filled up through interview, mostly of groups and sometimes of individual people. The justification of selection of people for the questionnaire survey was that the targeted people were familiar with the top-dying problem in Sundarbans, and are related through their professions with Sundarbans directly and indirectly. The questionnaire started by establishing that the respondents were familiar with top-dying, and went on to seek their views and information on what changes they had observed and whether they had noticed possible causes. This was possible because, most of the interviewees are living within the Sundarbans for their daily activities. So, this survey was performed to receive their indigenous response and knowledge towards top dying and its present conditions, and their ideas about what leads to top-dying, as well as questions about tree regeneration and human health in Sundarbans (Awal, 2014).

2.1.5. Statistical Analysis

Initial statistical analysis of quantitative data, particularly of the elemental concentrations, consisted of calculation of arithmetic means, standard deviations and standard error values for each variable separately. Data on the severity of top-dying for each tree in a plot, which had been recorded as 'not affected', 'mildly affected', 'moderately affected', and 'highly affected', were converted into a four-point scale (0-3), so that they could be summed and an average (median) could be determined for each plot, thus producing an index based on ranked data. Comparisons of the strength of relationship between two variables were assessed by correlation: the Pearson's product-moment correlation coefficient where both variables were fully quantitative or the Spearman's rank correlation coefficient where the top-dying index was one of the variables. In the case of the Spearman's coefficient, the probability of the outcome was determined by using the approximation to a t-statistic appropriate to these tests (Sokal

and Rohlf, 1981). Occasionally, a Pearson's correlation coefficient was calculated where top-dying was one of the variables, in order to check on the extent of the difference between the rank and quantitative versions for these data. Data on frequencies of seedlings or saplings in each of the plots and compartments were tested by χ^2 contingency table analysis to determine whether there was an association between the selected plot type (severely, moderately or little affected by top-dying) and the three chosen compartments. A similar consideration of the different compartments as comprising one factor, and the plot type as a second, was used to test the pattern of elemental concentrations and other variables by a 2-factor analysis of variance test with replication. This allows an assessment of the significance, not only of the two factors separately but also of the interaction term linking the two factors. It should be noted that the plot type was not a strictly controlled factor, since the three categories of top-dying intensity were relative to each other within any one compartment and might not have been exactly equivalent between the three categories; interpretation of the

results from these tests therefore needs to bear this in mind. MINITAB Release 14 Statistical Software has been used for windows on CD-ROM, 2004 edition for all data analysis, both statistical and graphical, except for those produced automatically by the Excel package attached to the ICPMS.

3. Results

These results are indicated as follows: if one number (all values in ppb) is given it is a mean, otherwise if a range is given they are the minimum and maximum; the number is followed by the type of material from which the data come, with no text indicating it is from sediments (the most common material reported in the literature); finally, the number in brackets indicates the numbered reference source, the sources being indicated in the legend. Besides attempting to establish whether the element concentrations are elevated or not, it is valuable to explore whether there is any marked spatial (as opposed to random) variation in the concentrations found.

Table 4.0. Mean (± 1 S.E.) and extreme heavy-metal elemental concentrations (ppb) in Sundarbans, together with comparisons with values from other published sources. An asterisk denotes a value below the limits of detection. Comparable data could not be found for all elements.

4. Discussion

Coastal lands cover 6% of the world's land surface (Tiner, 1984). Coastal and wetlands everywhere are under threat from agricultural intensification, pollution, major engineering schemes and urban development (UN-ESCAP 1987; 1988). The Indo-Pacific region is known for its luxuriant mangroves. The distribution of mangroves in the Indo-West Pacific biogeographical region has been outlined in Macnae (1968). However, the mangroves in half of these countries, as well as those of other regions, have since been destroyed through various pollution problems and population pressure (Peters *et al.*, 1985). The country's food security and public health will be in danger if the water and wetlands are destroyed at the present rate (Awal, 2009). Unplanned natural resources management and environmental contamination in Sundarbans are fast destroying the surface, vegetation, water, and underground fresh water sources (Awal, 2014). The primary source of fresh water for fishes, trees, human's health in Bangladesh was vital but due to heavy-metal contaminations in soil, water, faulty-vegetation management and deforestations of trees, top-dying disease and other diseases and health problems, irrigation for food production, industrialization, and public health, while industrial pollution and poor sanitation are making surface water unusable (Awal, 2007). The health of vegetation including natural flora & fauna, drinking water, soil are largely depends on uncontaminated groundwater (Awal, 2009). Water related diseases are responsible for 80 percent of all deaths in the developing world (Awal, 2014). Data were summarized by calculating means and standard errors, and by noting minimum and maximum values, for comparison with other data reported in the literature. The spatial variability in the data was assessed by calculating two-factor analyses of variance with replication, where the factors used were the broad-scale variation between compartments, the smaller-scale variation between plots within the same compartment, and the interaction between these two sources of variation. Government of Bangladesh, (1993). The concentrations of the various trace metals determined by ICP-MS from our Sundarbans soils are given in Table 4. For completeness, the minimum and maximum values are given, as well as the mean and the standard error, in order to facilitate comparisons with other published information and to indicate the extent of variability between the different samples in the results. It is clear that due to destruction of natural resources and contaminations of soil, water for some elements the variability is considerable; for example, nickel has a maximum value many times larger than the mean, while for iron the mean and maximum are more similar but the minimum is substantially smaller.

In order to try and establish whether these values are elevated compared to other data, comparison values are included in Table 2 from results published in the literature concerning the Bay of Bengal region. In order to assess this, an analysis of variance has been performed for each element separately, testing for location by using the compartment

from which the samples were taken as one factor, and the plot number within each compartment as a second factor, testing also for interaction between these two sources of variation. The results of these analyses are presented in Table 4, showing only those elements which showed at least one F-value at or near significance. Most of the elements tested do not show any significant variation related to any of these factors, and may therefore be considered to be relatively uniform or non-consistently variable in their concentrations, at least across the compartments studied here. There were no elements that proved significant when comparing between plots, nor in the interaction term, although antimony had a close result for the plot term ($p = 0.06$). However, a few elements did give significant results comparing between compartments, namely bismuth, scandium, strontium and vanadium. In all four cases, the lowest recorded concentrations were from compartment number 28; in all cases except for strontium, the compartment where the highest elemental concentrations were recorded was number 26 (compartment 31 being the highest for strontium). Interestingly, a similar analysis of concentrations (not presented separately here) also showed significant differences between compartments for sodium and phosphorus, with compartment 28 again having the lowest recorded concentrations.

In particular, the metal values from sediments are likely to be much higher than those from soils, and indeed one author (Balasubramanian, reported by Swaminathan, 2000) found sediment values to be often at least one thousand times higher than values for equivalent soils. The concentration values for the various trace metals recorded in Table 4 are believed to be amongst the first published for soils from the Sundarbans, and as such provide baseline data for comparison with other future studies in the area. It has therefore not been possible in many instances to find appropriate comparators from the literature in order to help assess whether the data show elevated concentrations from those expected in such soils. The comparative information from the literature presented in Table 4.0 is all from the same general region, but includes values from water (from ocean, springs or wells), from coastal soils (but not within the main mangrove areas), and particularly from mangrove sediments, as well as a few from mangrove soils. All comments based on these other sources must therefore be judged on the basis of the differences between the materials in the results likely to be obtained. A further complicating factor in interpreting these results is the high degree of variability in concentrations between different samples shown by many elements, as indicated in Table 4.0 by the high standard error values and by the results highlighted for some elements in Table 4.0.

For most of the elements tabulated there are either no comparisons in the literature, or the results from our study do not appear particularly elevated compared to other results. Perhaps surprisingly, given the problems that have been identified with elevated concentrations of arsenic (As) in groundwater in Bangladesh (e.g. Nickson *et al.*, 1998; Chowdhury *et al.*, 2000),

this element was not notably high in the soils studied here. However, there were other metals which may be elevated in their concentrations. Two results appeared particularly elevated, namely those for mercury (Hg) and for nickel (Ni). In considering the result for mercury, it is recognized that the ICP-MS method of testing the soils is not the most appropriate one for obtaining an accurate determination of mercury concentration because of the potential for cross-contamination of samples from earlier ones due to retention of the element within the instrument. The problem was reduced by the use of gold-wash solution rather than nitric acid in preparation of the calibration standards. Nonetheless, the elevated concentrations of mercury in these mangrove soils can only be considered as an indication until confirmation of these values by further work involving a different analytical procedure can be completed.

There is likely to be considerable geographic variation in the extent of pollution problems in the different parts of the Sundarbans, associated both with the proximity to local polluting sources such as Mongla port and with the extent to which the area is influenced by the Ganges river, which is strongly polluted (Sarkar *et al.*, 2003). This was indeed found (Table 4) as there were significant differences between different areas in the Sundarbans with regard to at least some of the elements studied, and others were probably not significant only because of the large amount of variability between different samples within individual compartments. It is therefore perhaps not surprising that the values reported by Zöckler and Bunting (2006) were lower than ours, since their study was in the east of Bangladesh away from the Ganges and other main sources of pollutants. Also, the choice of sites in the present work emphasised areas likely to be polluted because they were near to human activity and hence more accessible. Even so, and allowing for the fact that sediment data is the only comparator medium, the data from the literature suggest that the Sundarbans is not yet as polluted as some other mangroves from the region, such as in Pakistan (e.g. IUCN, 1987).

Clearly, further work is required to confirm and extend the results reported here. The indications of potentially elevated heavy metal concentrations is a matter of concern, and a higher general pollution load is likely to contribute to the increase in top-dying observed in the Sundarbans (Rahman, 2003; Chaffey, *et al.*, 1985; Chowdhury, 1984; Gibson, 1975). A likely mechanism of influence might be that greater concentrations of the trace-metals weaken the resistance of the tree to attack by pathogenic fungi. The relationship between individual trace metals and the amount of top-dying will be explored further in a separate article. It is also worth noting that local residents and those who work in the Sundarbans quite frequently reported health problems, of which problems of the skin were the most common (data from a questionnaire, included in Awal, 2007). It is possible that the high concentration of nickel (Awal, 2007), which can cause skin conditions, is leading to such complaints. Such health issues are therefore also a cause of concern and need further confirmation and elaboration.

5. Conclusion

Trees are essential part of the planets' ecological system (Awal, 2007, 2009, 2014), no one has the right to destroy the forest as it belongs to anybody; it belongs to the world. These natural trees comply with several functions, crucial for the health of this planet. The two principal functions are that they absorb the 'heat' and regulate the atmosphere temperature, captured by the carbon by 'blocking' the sun rays, and also absorbing and transforming CO₂ into oxygen (Awal, 2014). So, the destroying the forest, the destroying the earth's cooling system and pollution cleaner will be responsible for global warming, climate change. But, the natural function of trees and carbon—carbon captures the sun light, sent to earth by the sun, trees captures carbon and convert it into oxygen—it seem to us that the 'global warming' is temporary and internal (Awal, 2009). However the overall conclusions from the results presented in this section are that the selection of sites has not produced clear statistical differences in the amount of top-dying evident; probably because of the way the data were collected. However, it is believed that there is notable variation between plots and compartments, and certainly this seems to be reflected in the ability of the trees to regenerate. However, the link between top-dying and the size of the trees is not clear, with tree height and diameter not being directly related consistently to amount of top-dying, although moisture content of soil was inversely related. Since the great majority of trees present in all plots is the species *Heritiera fomes*, this means that the comments above are essentially referring to the response of this species rather than that of any others. So that, the Sundri, by contrast, prefers largely fresh water in which it resembles the mesophytes, but the species is adapted to the wet swampy condition of the Sundarbans by virtue of its leaves having partly xerophytic adaptations and plentiful pneumatophores which help cope with the saline swamps of the Sundarbans. The vegetations need sound ecological balanced to survive but due to deforestations, illicit fellings, human destruction are responsible for the heavy metal contaminations in soil, water and vegetation (Awal, 2007).

Comparing figures in the table 4.0, it would suggest that about two thirds of the elements have concentrations which are elevated compare to other reference sources in the Sundarbans. This would be consistent with the evidence that heavy metals were having an influence on top-dying intensity (Awal, 2007, 2009, 2014). The elements Pb, Sn, and Zn were highlighted earlier in this discussion, and although not all of them quite reached statistical significance (Awal, 2007), the positive trend linking two of them to top-dying suggests a likely mechanism of influence, namely that greater concentration of the heavy-metal weaken the resistance of the tree to attack by the pathogenic fungi (Awal, 2007, 2009, 20014). This might well be a process that other elements contribute to as well (Awal, 2007, 2009, 2014), but has not been picked out by the analysis as showing a link because of the variability between samples inherent in the data (Awal, 2007). In this respect, the anomaly of the negative relationship indicated for Sn is harder to

explain (Awal, 2007), but a possible process might be an antagonistic response of Sn and another element (Awal, 2007), so that when Sn is less abundant the other element can have a stronger (deleterious) effect on the trees (Awal, 2007), thus allowing more top-dying to occur (Awal, 2007). A further point is that variations in soil pH from site to site (shown to be significant) will also have a marked effect on the bio-availability of some of these heavy metals (Awal, 2007), and thus perhaps influence top-dying (Awal, 2007). We should protect natural resources such as Sundarbans in Bangladesh (Awal, 2009), because the future of Sundarbans is as directly dependent on the health of her wetlands, as is the future flora and fauna. Considering the limitations of the current planning process in Bangladesh, it is possible that within a few short decades, as water tables fall, rivers run dry and lakes shrivel, water-riots will become the order of the day. It may also be the case that wars on the subcontinent will more likely be fought over water than oil. And until uncontrolled development is restricted, the threat of floods and droughts due to loss of mangrove systems will continue to be present (Sahgal, 1991). Coastal lands include some of the most productive of ecosystems with a wide range of natural functions, but are also one of the most threatened habitats because of their vulnerability and attractiveness for 'development'. The first global conservation convention, the Ramsar Convention, focused solely on coastal lands and wetlands, and it has recently been strengthened and elaborated with regard to the wise use of all coastal areas such as Sundarbans.

Acknowledgements

My research work was supported financially by the Peoples' Republic of Bangladesh and the Asian Development Bank (ADB), whom I thank. Particular thanks are due to the ADB head office, Manila for their support and help. I thank sincerely Dr. W.G.H. Hale (Principal Supervisor), University of Bradford, UK, Professor Mike Ashmore (Technical Supervisor), University of York, UK and Dr. P.J. Hogarth for their advice and comments on the work; Dr. Ben Stern and the staff at the Analytical Centre, Bradford, for their help with the ICPMS analyses; Professor Sirajul Hoque, Mustafa (lab Technician) and staff at Dhaka University for providing facilities; and staff of the Forestry Service, Bangladesh Government, for field assistance. Moreover I indebted to my beloved parents Munshi Aowlad Hossain (Father: Teacher and Landlord as well as blossom friend of poor), Mrs. Ashrafunnessa (Mother: born Literate and Socialist, pious and friend of poor and distress), my venerated forefathers: Abadat Biswas (Mighty-Landlord), Golam-Rabbani-Biswas (Mighty-Landlord) my esteemed grandfathers (Munshi Bellal Hossain Biswas (Learned-Literate-Landlord), Md. Ataher (Lawyer and Powerful Jotdar and Landlord), my respected grand-mothers: Rohima Khatun (pious & friend of poor), and Alimoonnessa (social, pious and friend of poor and distress) my beloved wife (Dr. Shahana Khatun), my beloved son (Munshi Tasneem Redowan), my beloved daughter (Marwa Ashra), my beloved brothers: Munshi Abul

Kalam Azad (Officer in BAF), and Munshi Abdus Salam (Program Officer in UNDP), Munshi Abdul Rouf (Businessman), Motiar Rahman (Local Leader and social worker), and my beloved 6 sisters (Layla Anjumand Banu (Chandu), Akter Rashida Banu (Turi), Saleha Pervin (Lili), Azmeri Ferdowsi (Dolly), Jannatul Ferdowsi (Polly) and my beloved youngest sister Bedowra Ferdowsi (Jolly), my respected only uncle Munshi Abdur Razzak (Teacher and Jotdar as well as blossom Friend of poor people), my venerated maternal uncles: Anowarul Azim (Director of Family Planning), Amirul Azim (First Class-Magistrate and UNO), Aftabul Azim (Banker), Azizul Azim (Influential Leader and Govt.-Officer in Land Department), Anisul Azim (Social Leader and influential-Businessman), Aminul Azim (Dramatist), my respected Khalas (Khuki, Bulbul), as well as all family members for their inspiration and help.
