Abstract: Many researchers investigated different ways of improving the mixing inside a square lid-driven cavity by proper modification of the cavity geometric configuration. The present paper investigates the characteristics of the vortical structure inside a lid-driven square cavity with a central obstacle at different Reynolds numbers. The Multiple-Relaxation-Time Lattice Boltzmann Method (MRTLBM) is used to model the flow at Reynolds numbers between 100 and 1000. The results show that the position and shape of the main cavity is highly sensitive to the flow Reynolds number while the two lower side vortices are not affected by the change of the Reynolds number or the presence of the obstacle compared to the standard lid-driven cavity case. The reported results were verified against the standard lid-driven cavity case and showed good agreement. The results also show that adding a central obstacle to the standard cavity configuration can dramatically enhance its mixing capability. The reported results have significant importance for the enhancement of the mixing mechanisms inside the cavity for heat and mass transfer applications.

Keywords: Square Cavity, Vortical Structure, Central Obstacle, Multiple-Relaxation-Time Lattice Boltzmann Method

1. Introduction

The lid-driven cavity flow is a standard benchmark problem for any computational fluid dynamics technique [1-4]. Because it involves a circulating flow and high shear rate zones, it has been selected for benchmarking new CFD methods for their suitability and accuracy. Recently, the interest in studying different variants of the standard lid-driven cavity case has grown [5-7]. The unique features of this flow problem encouraged many researchers to use it for applications where better mixing and heat transfer rates are needed [8-11].

The cavity flow is characterized by its unique vortical structure which consists of a central main vortex and two lower side vortices [12] which involves high velocity gradients and shear rates. Modification of the standard lid-driven case allows the improvement of its unique features and encourages further investigation of its suitability for applications requiring these features.

The effect of the change in the geometric configuration of

the standard square lid-driven cavity on the hydrodynamic and thermal fields inside the cavity has been studied by many researchers [11, 13-15] however these studies lacked an extensive investigation of the effect of adding a central obstacle on the hydrodynamic field inside the cavity.

The main goal of this paper is to investigate the characteristics of the vortical structure in a square cavity with a central obstacle at different Reynolds numbers. The Multiple-Relaxation-Time Lattice Boltzmann Method is used for the simulation of the flow field in the cavity for Reynolds numbers between 100 and 1000. The change in the properties of the vortices with the Reynolds number is investigated. The reported results include the flow streamlines, the velocity profiles at the mid-plane of the cavity and the velocity contours. The conclusion section then summarizes the paper findings.

2. The Physical Domain

The modeled geometry consists of a square cavity with a central square obstacle. The flow inside the cavity is driven

by the movement of the top boundary with a horizontal velocity. Figure 1 shows a schematic of the modeled geometry and the used boundary condition. Note that the standard lid-driven cavity flow case does not include the central obstacle. In the standard lid-drive cavity case, three vortices develop inside the cavity, central one and two side ones on the two lower corners. The effect of adding the central obstacle on the structure of these vortices will be explained in the results section.

3. The Multiple-Relaxation-Time Lattice Boltzmann Method

The LBM solves the Boltzmann equation in a discrete form using a specific set of velocity directions. The discrete Boltzmann equation is given by:

$$f_i(x_i + c\Delta t, t + \Delta t) - f_i(x_i, t) = \Omega(f) \quad (1)$$

Figure 1. The modeled geometry and boundary conditions.

f_i is the particle distribution function along direction i , c is the lattice speed $c = \Delta x / \Delta t$ and $\Omega(f)$ is the collision operator. For the $D2Q9$ lattice, the directional velocities c_i are given by:

$$c_i = \begin{cases} (0,0) & i = 0 \\ (\pm 1, 0) & i = 1:4 \\ (\pm 1, \pm 1) & i = 5:8 \end{cases} \quad (2)$$

For the standard LBM $\Omega(f)$ is replaced by the *Bhatnagar–Gross–Krook (BGK)* collision operator [16]. Due to many limitations of the standard LBM, the MRT LBM is used. In the MRT LBM the collision operator is given by:

$$\Omega(f) = -M^{-1} \cdot S \cdot [m - m^{eq}] \quad (3)$$

M is a transformation matrix to transform the particle distribution function f from the velocity space to the moment space. The equilibrium distribution function f^{eq} is also transformed to m^{eq} .

$$M = \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ -4 & -1 & -1 & -1 & -1 & 2 & 2 & 2 & 2 \\ 4 & -2 & -2 & -2 & -2 & 1 & 1 & 1 & 1 \\ 0 & 1 & 0 & -1 & 0 & 1 & -1 & -1 & 1 \\ 0 & -2 & 0 & 2 & 0 & 1 & -1 & -1 & 1 \\ 0 & 0 & 1 & 0 & -1 & 1 & 1 & -1 & 1 \\ 0 & 0 & -2 & 0 & 2 & 1 & 1 & -1 & -1 \\ 0 & 1 & -1 & 1 & -1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & -1 & 1 & -1 \end{bmatrix} \quad (4)$$

S is the diagonal relaxation matrix.

$$S = \text{diag}(0, s_1, s_2, 0, s_4, 0, s_6, s_v, s_v) \quad (5)$$

For the $D2Q9$ lattice, the sonic speed is given by:

$$c_s = \frac{c}{\sqrt{3}} \quad (6)$$

The kinematic viscosity ν is related to s_v by the following relation:

$$\nu = c_s^2 \left(\frac{1}{s_v} - \frac{1}{2} \right) \quad (7)$$

The equilibrium particle distribution function f^{eq} is given by:

$$f_i^{eq} = w_i \rho \left[1 + \frac{c_i \cdot u}{c_s^2} + \frac{(c_i \cdot u)^2}{2c_s^4} - \frac{u \cdot u}{2c_s^2} \right] \quad (8)$$

And the macroscopic density ρ and velocity u are given by:

$$\rho(x, t) = \sum_i f_i(x, t) \quad (9)$$

$$u_j(x, t) = \frac{1}{\rho(x, t)} \sum_i c_{ij} f_i(x, t) \quad (10)$$

Figure 2. The steady state streamlines.

The used MRT LBM numerical model results were verified by simulating the flow in a standard lid-driven cavity flow at different Reynolds numbers and comparing the results to the ones given in literature. Table1 shows the location of the center of the main vortex predicted by the current model and the ones published in literature.

5. Numerical Results

The MRT LBM numerical method is used to model the flow in a square cavity with a central square obstacle. The central obstacle edge size is 30 % of the square cavity edge size.

The results include the streamlines, the velocity contours and the velocity profiles for the horizontal and vertical components at different sections inside the cavity.

Figure2 shows the streamlines for selected Reynolds numbers. Due to the presence of the central obstacle, the main vortex at the center of the cavity has moved to the top which results in a much smaller size for the vortex and higher velocity gradient. The figure shows that with the increase in the Reynolds number, the top vortex becomes smaller and moves downwards. At high Reynolds numbers (more than 600) the vortex is squeezed more against the top and right sides of the central obstacle.

Figure 3 shows the velocity contours for selected Reynolds number. It is clear that the presence of the central obstacles resulted in a much lower velocity at the center of the cavity.

To confirm the presence of higher gradients especially near the top boundary, the horizontal and vertical velocity components are plotted at the mid-vertical and mid-horizontal planes inside the cavity. The profiles shown in Figure 4 show a very high gradient especially for the horizontal velocity component.

6. Conclusion

The Multiple-Relaxation-Time Lattice Boltzmann Method is used to model the flow in a square lid-driven cavity with a central square obstacle at a wide range of Reynolds numbers. The results showed the change in the location and size of the central cavity with the change in the Reynolds number. The calculated velocity profiles at deferent sections inside the cavity confirm the high velocity gradients and shear rates compared to the stander lid-driven cavity case. The higher velocity gradients are very beneficial for increasing the mixing and heat transfer efficiency for heat and mass transfer applications.
