American Journal of Civil Engineering. Vol. 4, No. 3, 2016, pp. 74-79. doi: 10.11648/j.ajce.20160403.12

Received: March 25, 2016; **Accepted:** April 5, 2016; **Published:** April 26, 2016

Abstract: This project evaluates the performance of pozzolona cement elements produced from alternative raw materials with a view using them in low-cost housing. It also seeks the reduction of waste from agricultural sources and the cost of sandcrete blocks by using locally available materials. The need to find alternative materials to replace existing conventional ones has necessitated research into substitutes to cement with a view to investigating their usefulness to wholly or partly substitute ordinary Portland cement in the production of sandcrete blocks. This project investigates the possible use of Corn Cob Ash (CCA) as a partial replacement of cement in sandcrete block production. 140 no. 450mmx150mmx225mm solid sandcrete blocks of mix ratio 1:8 were cast, cured and crushed at 7, 14, 21, and 28 days. The corn cob ash was replaced at 0 to 40 percent levels at 5% intervals. The maximum compressive strength of 2.10 N/mm² was recorded at 30% replacement on the 28th day. After 12 months of exposure under northern savannah climatic conditions, the compressive strength remained stable or even increased with the weathering exposure. The maximum value of 2.10N/mm² for the 30% replacement level is found suitable and recommended for building construction having attained a 28-day compressive strength of more than 2.0N/mm² as required by the National Building Code for non load bearing walls.

Keywords: Pozzolona-Cement, Construction Materials, Low-Cost Housing, Sandcrete, Corn Cob Ash, Northern Savannah, Ghana

1. Introduction

The importance of sandcrete blocks as part of local building materials cannot be over emphasized in building and construction industry in Ghana. Sandcrete blocks have been widely used for building construction in the country in general and are increasingly replacing mud and stabilized earth as a walling material in the savannah ecological zone. The rapid adoption of these blocks has encouraged investigations into ways to make it more efficient and affordable. It is also an observable fact that river sand which is an important ingredient in making sandcrete blocks is widely available in the study area as a result of the many rivers and water bodies that traverse it.

Maize is the most important cereal crop produced in Ghana and it is also the most widely consumed staple food in Ghana with increasing production since 1965 (FAO, 2008; Morris *et al.*, 1999). In Ghana, maize is produced predominantly by smallholder resource poor farmers under

rain-fed conditions (SARI, 1996). With these quantities comes the accompanying waste from corn husk and cob.

The cost of cement is a major issue for many builders in the study area. Therefore exploring the possible use of a commonly occurring waste material as a cement substitute will constitute an equally major relief for builders.

2. Theoretical Framework

Sandcrete blocks are composite material made up of cement, sand and water, moulded into different sizes. It is widely used in Ghana as a walling unit. The quality of blocks produced however, differs from due to the different methods employed in the production and the properties of the constituent materials.

Cement is a material with cohesive and adhesive properties when mixed with water, which makes it capable of bonding material fragments into a compact whole (Neville, 1996). Cements are classified as calcium silicate

and calcium aluminate cement. Calcium silicate cement is further classified into Portland and Slag, while calcium aluminate is classified into High alumina and Pozzolona cement (Jackson and Dhir, 1991). Corn husk and cob has recently been recognized as pozzolona. A pozzolona is a siliceous/ aluminous material which in itself has little or no cementitious value, but which will in finely divided form and in the presence of moisture, chemically reacts with calcium hydroxide liberated during the hydration of Portland cement to produce stable, insoluble cementitious compound which contributes to its strength and impermeability (Sima, 1974).

Corn husk and cob ash is one of the promising pozzolanic materials that can be blended with Portland cement for the production of durable concrete/ blocks and at the same time it is a value added product. Addition of corn husk/cob ash to Portland cement does not only improve the early strength of concrete/block, but also forms a calcium silicate hydrate (CSH) gel around the cement particles which is highly dense and less porous, and may increase the strength of concrete/block against cracking (Saraswathy and Ha- Won, 2007).

Many countries including Ghana have the problem of shortage of conventional cementing materials. Recently there are considerable efforts worldwide of utilizing indigenous and waste, materials in concrete. One of such materials is the corn husk/cob which under controlled burning, and if sufficiently ground, the ash that is produced can be used as a cement replacement material in concrete (Anwar *et al*, 2000). Corn husks/cobs are used as building materials; lightweight concrete briquettes have been made from partly burnt husks/cobs. Insulating blocks have also been made with cement and husk ash that resists very high temperatures (Grith, 1974).

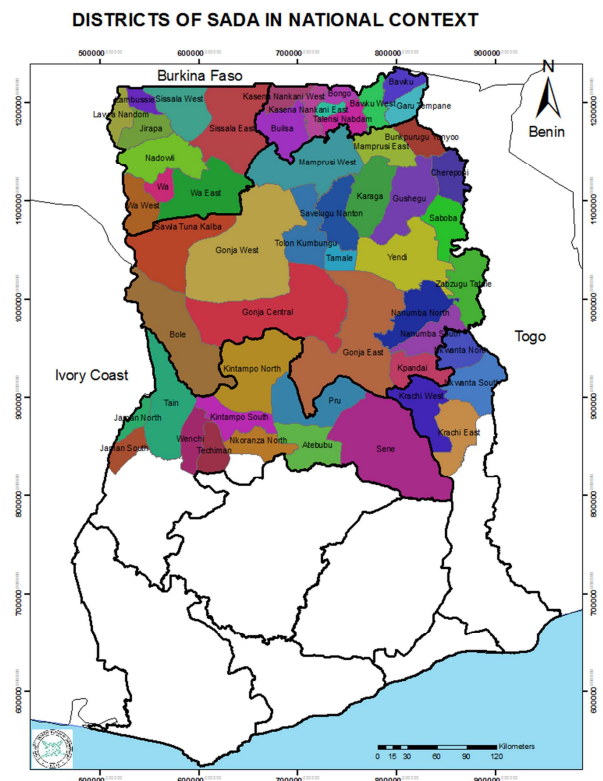

Corn cob is the hard thick cylindrical central core of maize (on which are borne the grains or kernels of an ear of corn). Raheem (2010) described Corn cob as the agricultural waste product obtained from maize or corn; which is the most important cereal crop in sub-Saharan Africa. There had been various research efforts on the use of corn cob ash (CCA) and other pozzolona as a replacement for cement in concrete. Olutoge *et al*(2010); presented a comparative study on fly ash and ground granulated blast furnace slag (GGBS) high performance concrete, Ogunfolami (1995); considered mixing of the CCA with Ordinary Portland cement at the point of need (i.e. on site). Adesanya and Raheem (2010); studied the workability and compressive strength characteristics of Corn cob ash (CCA) blended cement concrete. Adesanya and Raheem (2009); also assessed the development of Corn cob ash (CCA) Blended Cement.

3. Materials and Methods

3.1. Study Area

The data were collected between January and September, 2013 in the five regions (Northern, Upper East, Upper West

and the northern Brong Ahafo and Volta regions as shown in Figure 1 below) of Northern Ghana. This area also referred to as the northern savannah ecological zone in Ghana makes up about 48% of the country's total land area. Rainfall distribution is uni-modal giving a single growing season of 180 to 200 days with an annual mean of 1,100 mm. The dry season starts in November and ends in March/April with maximum temperatures of about 42°C occurring towards the end of the dry season. The data collection was carried out in six districts across the zone, two districts in each of the three regions and one district each from northern Volta and Brong Ahafo.

Source: SADA (Savannah Accelerated Development Authority)

Figure 1. A map of Ghana showing the study area.

3.2. Materials

3.2.1. Sand

The Sand used was clean, sharp river sand that was free from clay obtained from Dalung near Tamale in the Northern Region. The sand had a specific gravity of 2.60.

3.2.2. Cement

The cement used was ordinary Portland cement from the Savannah cement company, located in Buipe in the Northern Region with properties conforming to BS 12(1971). The properties of the cement are shown in Table 1.

3.2.3. Water

The water used was potable, fresh, colourless, odourless and tasteless water that is free from organic matter of any type.

3.2.4. Corn Husk/Cob Ash (CCA)

Corn husk and Cob used for this work was obtained from different farms located in the study area. The samples were allowed to dry under the sun for three days. The dried husk and cobs were burned slowly to ash in a gas kiln gradually for 3 days at 1100°C to obtain a finely divided ash, which is then sieved and kept ready for analysis (Rice Husk Ash, 2009). Chemical analysis of CCA was carried out in the laboratory of Chemistry Department at the Kwame Nkrumah University of Science and Technology. The properties are shown in Table 1.

3.3. Manufacture of Sandcrete Blocks

In this study, the solid blocks were manufactured with the use of the fabricating machine. One mix proportion of 1:8 was used in the production of 450mm x 225mm x 225mm sandcrete block. One hundred and forty of 450mmx150mmx225mm solid sandcrete blocks were produced. The quantities of materials obtained from the mix design were measured in each case by volume. The percentage of CCA content was varied in steps of 5% to a maximum of 40%. For the experiment, hand mixing was employed, and the materials were turned over a number of times until an even colour and consistency was attained. Water was then added as required through a water hose, and the materials were further turned over to secure adhesion. It was then rammed into the machine mould, compacted and smoothed off with a steel face tool.

After removal from the machine moulds, the blocks were left on pallets under cover and cured by watering through a fine watering hose. Testing for crushing strength was then carried out at 7, 14, 21 and 28 days.

4. Results and Discussion

The results are presented in tabular and graphical forms. Table 2 shows the results of the compressive strength test at various percentages of CCA contents. Figure 1 shows the plot of compressive strength against percentage CCA content at ages 7, 14, 21 and 28 days. Figure 2: shows the relationship between CCA content and compressive strength.

4.1. Effect of Corn Husk/Cob Ash on Compressive Strength

The compressive strength values show that the inclusion of CCA in the cement matrix does not appreciably enhance the compressive strength of the sandcrete blocks. At 5% replacement of CCA the compressive strength is 2.16N/mm², which is 15% less than the control value. Figure 2 revealed that there is decrease in compressive strength as the proportion of coconut husk ash increases in the mix. The reduction in compressive strength for the replacement is due to low percentage of Calcium Oxide and Silicate Oxide in coconut husk ash. These two silicates are the main constituent of cement and are mainly responsible for the strength development. So as the cement content is gradually replaced by the coconut husk ash, the quantity of cement for

hydration is reduced thereby the strength of the sandcrete blocks is reduced.

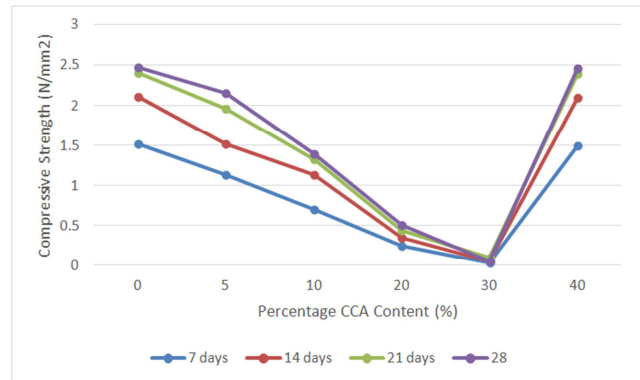

Figure 2. Diagram showing the relationship between CCA content and compressive strength.

The Nigeria National Building Code (16) recommended that average strength of 6 sandcrete block shall be 2.00N/mm² and lowest strength for individual block shall be 1.75N/mm² sandcrete block (18). For the 5% replacement of CCA in the cement matrix, the least value for the 28th day compressive strength is 2.03N/mm², higher than recommendation by the code.

4.2. Effect of CCA on Dry Density

There is inconsistency in the dry density of the mix for the ages, but the maximum dry density for all the ages occurred at 15% CHA replacement. The maximum value of 1945.90 Kg/m³ was recorded at 7 day test.

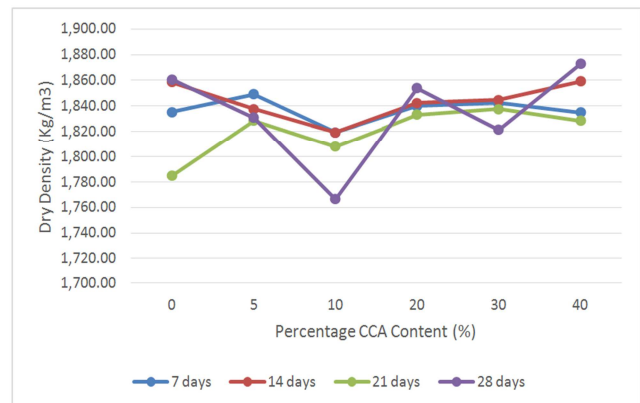

Figure 3. Diagram showing the relationship between dry density and CCA content.

4.3. Weathering Conditions

To determine the effect of weathering on the properties on the sandcrete blocks, the prepared samples that attained the desired compressive strength were exposed to the outdoor climatic conditions at various locations of the study area. The samples were exposed 28 days after manufacture in racks inclined 45° to ensure maximum exposure during the rainy and dry seasons.

The exposed specimens recorded stable or slight increases in compressive strength with no visible signs of deterioration.

5. Conclusion

The main conclusions derived from this investigation are as follows:

- Agriculture wastes such as corn cob/ husk ash shows good pozzolanic property in the production of sandcrete blocks.
- The maximum compressive strength of 2.16 N/mm² was obtained for the sandcrete block specimens at a percentage CCA content of 30%.
- Corn husk/cob ash addition should not exceed 30% of the weight of cement for best results.
- The maximum compressive strength achieved at 5% is more than recommendation of 2.00N/mm² recommended by National Building Code, for non load bearing walls.

Recommendation

1. Subsequent studies should be done on 0- 40% replacement of cement with corn cob ash and in steps of 5%.
2. Block/Concretes with the presence of ash content should be allowed to cure for 90days, by which pozzolanic activity of ash would have been concluded.
3. The use of locally available materials in infrastructure development will be met with the use of corn cob ash as a construction material and ultimately help meet our millennium development goals (MDG), thereby also enhancing the economic power of the rural dwellers if they are encouraged to plant maize from which these corn cobs could be gotten. The global green environment initiative will also be greatly influenced by the reduction in solid waste disposal.
4. The volume replacement attempted to get high strength concrete should be enhanced with super-plasticizers and a further reduction in the water-cement ratio so that concrete of very high strength can be achieved.

The following recommendations are drawn.

1. Use of other admixtures be incorporated with corn husk/cob ash in order to retard the hydration of water be studied
2. Other raw materials containing slightly higher calcium oxide and alumina could be used to improve the used of RHA as cement replacement.
1. Subsequent studies should be done on 0-40% replacement of cement with corn cob ash and in steps of 5%.
2. Concretes with the presence of ash content should be allowed to cure for 90days, by which pozzolanic activity of ash would have been concluded.
3. The use of locally available materials in infrastructure development will be met with the use of corn cob ash

as a construction material and ultimately help meet our millennium development goals (MDG), thereby also enhancing the economic power of the rural dwellers if they are encouraged to plant maize from which these corn cobs could be gotten. The global green environment initiative will also be greatly influenced by the reduction in solid waste disposal.

4. The volume replacement attempted to get high strength concrete should be enhanced with super-plasticizers and a further reduction in the water-cement ratio so that concrete of very high strength can be achieved.
