Phenotypic Variations of Endophytic Bacteria Associated with Carob Tree (*Ceratonia Siliqua* L.). *American Journal of Life Sciences*. Vol. 2, No. 5, 2014, pp. 325-332. doi: 10.11648/j.ajls.20140205.22

Abstract: We aimed to characterize 83 endophytic bacteria isolated from roots (73 isolates coded IRC) and epicotyls (11 isolates coded IEC) of young Carob (*Ceratonia siliqua* L.) seedlings. These seedlings were obtained from seeds collected in several regions in Morocco. 30 IRC and 4 IEC were selected on the basis of PCR-Pep for the further analyses. All the strains exhibited a wide tolerance to NaCl and 30 % tolerated well concentration up to 11 % NaCl. Strains showed also a wide tolerance to the variable pH. 60 % of strains grew well at pH4. Most of the strains were resistant to different antibiotics but were sensitive to kanamycin and tetracycline. The strains showed a resistance to heavy metals except mercury chloride that was toxic at a low concentration 50 µg.ml⁻¹. According to their phenotypical features, the associative bacteria were very similar to eight symbiotic bacteria previously identified by Missbah in 1996 and used in this work.

Keywords: Isolation, Associative Endophytic Bacteria, Phenotypic Characterization, Managed Ecosystem

1. Introduction

In managed ecosystems, plant-associated bacteria play a key role in host adaptation to a changing environment [1, 2, 3]. Microbial endophytic species are present in a wide range of plant species and reside either within cells, in the intercellular space or in the vascular system of plant [4].

The term endophyte was defined by De Bary [5] cited by Stone [6] and refers to mycotic flora that inhabits the interior of plant tissues. This term was then applied to bacteria and was the subject of several conceptual definitions [7]. In general, this term includes all microorganisms that are able to colonize, during some portion of their life cycle, the inner tissues of plants without causing any apparent damage to the host [8].

Interaction between plant and beneficial bacteria can have a profound effect on crop health and yield [3]. Bacteria known as Plant Growth-Promoting Rhizobacteria (PGPR) [9] that colonize root, can enhance shoot emergence and stimulate plant growth through production of auxins, gibberellins and cytokinins [10], induce plant defense mechanisms, produce antibiotic, out-compete pathogens and

improve soil structure [11-13, 14].

The faculty to infect and colonize roots has been considered the major factor that determine inoculum efficacy both for crop yield enhancement and for disease control [15]. Root colonization by endophytic bacteria occurs preferentially through the natural fissures resulting from the emergence of lateral root like lateral root cracks (LRCs) or on the root surface and root tips [16].

The flavonoids (naringenin and daizein) were found to stimulate significantly the LRC colonization of Wheat and *Arabidopsis thaliana* by *Azorhizobium caulinodans* ORS571, by *Azospirillum* and by *Herbaspirillum* [16, 17]. Inside the plant tissues, bacteria form a large intercellular infection pockets in which the endophyte divide, develop infection threads and interchange with host [18].

The potential of PGPR to fix atmospheric nitrogen and promote plant growth has renewed the interest in such associations. Patriquin et al. [19] demonstrated hormonal effects, biological nitrogen fixation and interference in other processes of the nitrogen assimilation of some bacteria associated with plants. For several uninoculated soil grown Gramineae, 15N-enriched tracer studies have shown that

microbial communities can fix substantial amounts of atmospheric N₂ [20, 21]. The activity of the enzyme Nitrogenase was detected, *in vitro* culture, inside the Carob roots and bourgeons [22]. The identification of diazotrophic bacteria responsible for N-gain is important for agricultural applications well as for understanding ecosystem processes [23, 24]. Non-rhizobial endophytic diazotrophs like *Azoarcus* spp., *Gluconacetobacter diazotrophicus*, *Herbaspirillum* spp. and *Burkholderia* spp. have been isolated respectively from kallar grass, sugarcane, rice and vine [25, 26, 27]. Recently, several researches demonstrated other behaviour of symbiotic rhizobia such as natural endophytes that can colonize interior tissues and increase the productivity of many leguminous or non-leguminous plants [28-32, 33, 34]. In Côte d'Ivoire, first producer of cocoa to the world, cultivation practices increase cocoa farms degradation [35] and cocoa diseases. Indigenous microorganisms of cocoa tree were identified as well as antagonist against *Phytophthora* sp, the causal agent of black pod disease [36].

Carob (*Ceratonia siliqua L.*) is an endemic leguminous tree of the Mediterranean region [37, 38]. It presents a great industrial and pharmaceutical importance [39, 40, 41]. Actually, Carob tree gain much attention since it is considered as an important component for re-vegetation and environmental conservation [39, 42].

In a previous investigation, we have observed from sterile sectioned parts of young seedlings used *in vitro* culture, the emergence of some bacterial strains. We were curious to know if endophytic bacteria can reside in internal tissues of Carob. In our knowledge, no investigation has concerned the finding of endophytic bacteria associated with Carob tree. Thus, the aims of the present work are: (i) to isolate endophytic bacteria from vegetative organs of Carob originating from seeds collected in different regions of Morocco; (ii) to characterize representative's strains by phenotypic features selected on the basis of PCR-Pep.

2. Material and Methods

2.1. Plant Material

The seeds used in this work were obtained from pods collected from 11 regions of Morocco: Taourirt, Al Houceima, Taounate, Ain Safa, Akchort, Demnate, Ouazzane, Sidi Bou Othmane, Essaouira, Tetouan and Ouad Lou. Each collection of seeds was referred to its original region as a separate accession. Soil sample were also collected in each region.

Seeds were scarified by H₂SO₄ at 95%. After the germination of seeds on sterile water agar (0.7% w/v), plates were incubated at 28°C in obscurity. The young seedlings were transferred in pots containing soil of the same origin then placed in a growth chamber.

2.2. Isolation of Endophytic Bacteria

After six months of cultivation (Figure 1 a), roots and epicotyls of young Carob seedlings were used for bacterial isolation.

Figure 1. Carob seedlings in cultivation (a)- roots of young Carob tree, (b) filament and finger (rectangle) forms.

2.2.1. Isolation from Roots

The roots of Carob tree were not uniform. We have found filament and finger forms (Figure 1 b). Finger forms of roots, was washed several times with sterile water, sterilized with 0.1% HgCl₂ for 5min under vigorous shaking, and washed thoroughly with sterile water and then ground with 1mL of pure water. The mixed tissue (0.5 mL) was spotted on YEM medium [43] and incubated at 28°C.

2.2.2. Isolation from Epicotyls

Epicotyls were successively treated with SDS (0.01%) for 2 h, with HgCl₂ (0.2%) for 10min then washed with sterile water. Epicotyls portions of 0.5 cm to 1 cm were sectioned, transferred on sterile water agar plates (0.7% w/v) then incubated at 28°C.

2.3. Phenotypic Features

30 IRC and 4 IEC strains representing the various PCR-Rep groups and also 8 strains nodulating Carob (RCM) previously identified by Missbah *et al.* [44] were used to realize further analyses.

All tests were carried out on YEM agar plates. Petri dishes containing YEM medium were subdivided into squares and each square was inoculated with 10µl of YEM broth bacterial culture. After 7 days of incubation at 28°C, bacterial growth was compared to the controls. Two replication tests were done for each treatment.

2.3.1. Salt Tolerance

It was conducted on agar plates at variable concentrations ranging from 1 to 12% NaCl (w/v).

2.3.2. pH Resistance

Tolerance to pH was tested on YEM plates set at different pH values, using the buffers MES (20mM) (SIGMA) for pHs ranging between 5.5 and 6.7, and MOPS (20 mM) (SIGMA) for pHs ranging between 6.7 and 7.9. The medium was buffered with HCl for pH values lower than 5.5 and with NaOH for pH values between 8 and 10.

2.3.3. Antibiotics Tolerance

The intrinsic resistance of strains was determined on solid YEM medium containing the following filter sterilized antibiotics: ampicillin, chloramphenicol, erythromycin, kanamycin, nalidixic acid, rifampicin, spectinomycin, streptomycin and tetracycline at variable concentrations ranging from 10 to 100 µgml⁻¹.

2.3.4. Heavy Metal Resistance

The resistance of strains to heavy metals was also determined on solid YEM medium. The stock solutions of metals were filter-sterilized and added to sterile agar as follows concentrations: CdCl₂, 10-50 µg/ml; AlCl₃, 400-500 µg/ml; HgCl₂, 50-100 µg/ml; MnCl₂, 500-600 µg/ml and ZnCl₂, 50-100 µg/ml.

3. Results

3.1. Root and Epicotyls Endophytic Bacteria

The isolation of endophytic bacteria from the vegetative organs of Carob seedlings harvested after six months of culture, in occurrence from roots and epicotyls, was very successful. However, the presence of bacteria in the two

organs was not found with plants of all accessions, for instance: Taourirt and al-Houceima (Table 1). Strains isolated from roots were coded as IRC (Isolates Root Carob) and similarly strains isolated from epicotyls were coded IEC (Isolates Epicotyle Carob).

A total of 73 endophytic bacteria were isolated from roots (IRC) and were obtained from 9 accessions. The high numbers of these endophytes were obtained from Taounate accession with 26% of isolates and from Ouazane accession with 20.5% of isolates. The lowest number was recorded from Akchort accession with 1.4% of isolates.

11 endophytic bacteria were isolated from epicotyls and were obtained with plants originating from 3 accessions. More than 50% of isolates were obtained from Sidi Bou Othaman accession while 9.1% were native to Essaouira (Table 1).

Table 1. Percentage of endophytic bacteria isolated from roots and epicotyls of Carob seedlings originating from different regions of Morocco.

Accession	Accession origin	Presence of endophytic bacteria (+) or (-)	Type of organ	% of IRC	% of IEC
1	Taourirt	-	-	-	-
2	Al Houceima	-	-	-	-
3	Taounate	+	Roots	26	36.4
4	Aïn Safa	+	Epicotyls		
5	Akchort	+	Roots	5.5	0
6	Demnate	+	Roots	1.4	0
7	Ouzane	+	Roots	9.6	0
8	Sidi Bou Othmane	+	Roots	20.5	0
9	Essaouira	+	Roots		
10	Tétouan	+	Epicotyls	4.1	54.5
11	Ouad Laou	+	Roots	4.1	9.1
			Epicotyls	16.4	0
			Roots	12.4	0
Total	11	73 from roots 11 from epicotyls		100	100

The dendrogram (PCR-Rep) constructed on pair-wise comparison of Rep fingerprints of all IRC, IEC and RCM strains, showed a high diversity (data not shown). In fact, we obtained 8 clusters and 18 independent lineages above 85 % of similarity level. The results allowed us to identify the exact number of strains in our collection. We obtained 65 different strains for root endophytes and only 3 strains for epicotyls endophytes. 30 IRC and 4 IEC strains representing the various groups were selected for the further analyses.

3.2. Phenotypic Features

42 strains originating from Carob, the 34 endophytic bacteria (30 IRC and 4 IEC) selected on the basis of Rep analysis and the 8 symbiotic bacteria RCM, were used in four phenotypic tests.

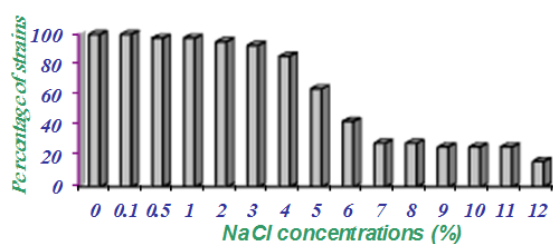

Figure 2. Tolerance of Carob strains to different concentrations of NaCl.

Salt tolerance: Figure 2 shows that all the strains exhibited a clear tolerance to the salt tested. More than 90 % of strains grew well from 1 to 3 % NaCl. At higher concentration, the percentage of tolerant strains decreased. However, more than 60% were tolerant to 5 % NaCl and about 30 % were tolerant to 11 % NaCl.

Figure 3. Tolerance of Carob strains to different pH.

pH tolerance: All the tested bacteria were uniformly tolerant to the variable pH tested (Figure 3). 90 % of strains grew well in slightly acid and acid pH. 60 % of strains were acid-tolerant exhibiting a marked tolerance at pH 4. However, at pH 3, most the strains were sensitive. In alkaline pH, strains were widely tolerant.

Antibiotics resistance: More than 60 % of strains exhibited a

high resistance to the concentration of 10 µl/ml of ampicillin, chloramphenicol, erythromycin, nalidixic-acid, spectinomycin and streptomycin while a lower percentage was recorded with kanamycin and tetracycline. This result was highly observed

with the other concentrations tested (50 and 100 µg/mL). The latest two antibiotics have significantly affected the growth of the bacteria. However, nalidixic acid produce a slight inhibitory effect on the growth of the different strains (Table 2).

Table 2. Effect of different antibiotics on growth of Carob endophytic bacteria and RCM strains.

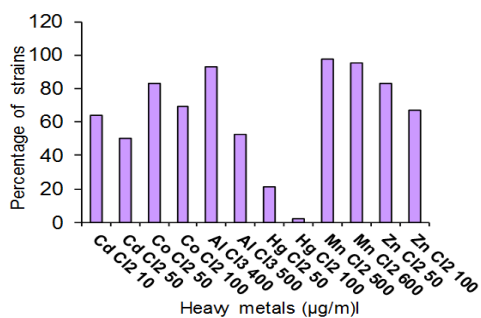

Figure 4. Effect of heavy metals on the growth of Carob associative bacteria.

Heavy metal resistance: The Carob associated bacteria showed a wide resistance to heavy metals tested (Figure 4). Except for a few number (18 %), all the strains were sensitive to mercury chloride. The others metals (cadmium, cobalt, aluminium, manganese and zinc), were less toxic on the growth of bacteria even at a higher concentration of 500 µg/ml. Manganese is the least toxic metal because even at very high concentrations, the growth of the strains were not affected. The aluminum concentration of 500 µg/ml inhibited half of the strains. For cobalt and zinc, more than 60 % of strains were resistant to a concentration of 100 µg/ml. For cadmium, 65 % of strains were resistant to a concentration of 50 µg/ml and the half

of the strains to 100 µg/ml.

4. Discussion

The present study demonstrates clearly that associative endophytic bacteria can reside in the internal tissues of the vegetative organs, in occurrence epicotyls and roots of Carob without inducing any obvious symptoms. Plants grown in natural soil eventually develop a continuum associative relationship with living microorganisms that can extend from the rhizosphere to the rhizoplane, deeply into the epidermis, the endodermis and through the vascular system [25, 34]. The endophytic habitat has been reported as an important pool for the isolation of N-fixing plant growth-promoting rhizobacteria [45]. The plant naturally select endophytes that can fit competitively to occupy compatible niches within its nutritionally-enriched and protected habitat of its internal tissues without causing pathological symptoms on the host plant [46].

Several authors reported the capacity of different bacteria to infect and colonize roots, stems, leaves or the system vascular of a wide range of monocotyledons and dicotyledons. In fact, many plants such as *Saccharum officinarum* [20, 47], *Sorghum bicolor* L. [48], *Triticum aestivum* [33, 49], *Oryza sativa* L. [33, 34, 50, 51], *Zea mays* L. [28, 52], *Gossypium* sp. [53, 54], *Vitis vinifera* [25, 55], *Lactuca sativa* [28], *Picea-abies* [56], *Coffea arabica* [57], *Helianthus petiolaris* [11], *Musa* spp. and *Ananas comosus* L. [58] are successively reported to establish beneficial association with different type of endophytic bacteria. This could strongly contribute to increase productivity and reduce disease in the agricultural practices in regard to the potential of these bacteria concerning their reaction to mineral concentration and antibiotics.

Roots and epicotyls endophytes were found with all plant accessions, except Al Houceima and Taourirt. A total of 73 endophytic bacteria was isolated. Most of the isolates originated from roots especially from Taounate and Oauzane accessions. However, 11 endophytic bacteria were isolated from epicotyls and were obtained only from three accessions. In Vietnam, 561 endophytic bacteria were isolated from stems and roots of 70 Rice plants [51].

PCR-Rep allowed us to determine the exact number of the different endophytes in the collection. Root endophytes showed to be more diverse than expected with a number of 65 strains while, epicotyls endophytes were represented by 3 distinct strains.

34 rep-based selected strains, for instance IEC and IRC, and 8 RCM strains were subject of three physiologic tests. Morphologically, Carob endophytic bacteria were found to be Gram-negative, non-spore-forming, motile and rods. The optimum temperature was 28 - 30°C. The colonies were circular, convex, smooth, raised, and mucilaginous, usually 2 - 4 mm in diameter within 3 - 5 on YEM medium. Strains exhibited a wide tolerance to salinity (NaCl). 15 % of strains showed a great osmotolerance since they were able to grow in 12 % NaCl. It was reported that *Bacillus endophyticus* sp. isolated from the internal tissues of cotton plants (*Gossypium*

sp.) presented an optimum growth in the presence of 10 % NaCl [54]. Rhizobia isolated from woody legumes like *Hedysarum*, *Acacia*, *Prosopis* and *Leucaena* can also tolerate high NaCl concentrations up to 500 and 800mM NaCl [59]. A strong salt tolerance was reported to aid in tolerance to high pH and temperature [60]. Many species of rhizobia were reported to develop adaptation to salinity stress by intracellular accumulation of compatible solute [61]. Salt tolerance strains can give them advantages to survive, multiply in saline soil and efficiency infect their host plants. Strains were uniformly tolerant to high pH. At low pH, 60 % of strains exhibited an acid-tolerant character since they grew well at pH 4. Some physiological studies showed that *Gluconacetobacter diazotrophicus*, endophyte of sugarcane, grew well at pH 5.5 and was able to grow at pH 3.0 and even to fix nitrogen in a culture medium at pH 2.5 [62]. *Spirillum lipoferum*, endophyte of *Digitaria*, has an optimum growth and Nitrogen fixing capacity at pH 6.8 to 7.8 [63]. Various rhizobial strains such as *R. tropici*, *R. leguminosarum* bv. *trifolii* and *Mesorhizobium loti*, were described as acid-tolerant and presented a good growth at pH 4 [64, 65, 66].

Strains were highly sensitive to tetracyclin and to kanamycin. But they were mostly resistant to nalidixic acid. They showed, however, a similar character in their resistance to the different concentrations tested of ampicillin, chloramphenicol, erythromycin, Nalidixic acid, spectinomycin and streptomycin. This result, indicate that strains exhibited a multiple antibiotic resistance. The same result was described for many rhizobacteria. Various strains belonging to the genus *Burkholderia* such as *B. vietnamiensis* isolated from rice exhibited a multiple antibiotic resistance [26]. Schwingamer [67] and Cole et al. [68] has described several strains of *Rhizobium* sp., resistants to several antibiotics. The rhizobia isolated from root-nodule of *Cicer arietinum* grew well in presence of 9 different antibiotics [66].

The level of heavy metal resistance exhibited by Carob associative bacteria, appears relatively high compared to what we know in general on rhizobia. Their resistance to metals is very similar to the behavior of rhizobium strains nodulating *Acacia* sp. [69], and slightly different from that exhibited by strains of rhizobia isolated from *Cicer arietinum* (64). In general, compared to various species of rhizobia, the endophytic bacteria from roots and epicotyls of Carob as well as those of the RCM collection exhibited good tolerance to heavy metals. This feature can be exploited later in the bioremediation trials aimed at improving the quality of soil contaminated with heavy metals sites.

5. Conclusion

We clearly demonstrate that rhizobacteria possess the faculty that allow them to be associate efficiently as natural endophytes with Carob tree (*Ceratonia siliqua* L.). So, our study, confirm the result obtained by Bryan et al. [22] who observed the enzyme Nitrogen-fixing activities in Carob roots and bourgeons internal for in vitro culture. Under laboratory conditions, the direct isolation of associative endophytic

bacteria, from vegetative organs of Carob, was successfully positive. 73 and 11 isolates were respectively recovered from roots and epicotyls of plants originating from eleven different regions of Morocco. Rep analysis showed a high level of diversity. The strains selected by Rep marker grew well in YEM alkaline medium and were also acid-tolerant. They were mostly osmotolerant and exhibited a multiple antibiotic and heavy metal resistances. These results could serve as a reference for future ecosystems management.
