Abstract: Neurotensin (NT) and an NT-related peptide (Lys, Asn, NT⁸⁻¹³; LANT-6) are produced in the chicken brain and intestine, and these peptides are encoded by the same precursor gene (NT/LANT-6 precursor). Although it has been reported that the central administration of NT suppresses food intake in mammals, the effect of NT and LANT-6 on feeding behavior in birds has not yet been investigated. In this paper, we analyzed the expression levels of NT/LANT-6 precursor and the NT receptor (NTR1) mRNAs in the hypothalamic infundibulum, an important region for regulating feeding behaviors. We also examined the effects of NT and LANT-6 administration on food intake in chicks. Real-time PCR analysis showed that NT/LANT-6 precursor and NTR1 mRNAs had moderately high expression in the hypothalamic infundibulum. Further, in the hypothalamic infundibulum, the mRNA level of NT/LANT-6 precursor showed a trend toward increasing during postnatal development and increased 2.9-fold after a 48 hour fast, although the NTR1 mRNA level was not changed in both analyses. Contrary to our expectations, central administration of NT or LANT-6 had no effect on food intake in chicks.

Keywords: Brain, Chicken, Food Intake, Hypothalamic Infundibulum, LANT-6, mRNA, Neurotensin

1. Introduction

Neurotensin (NT) is a 13-amino-acid peptide first isolated from the bovine hypothalamus [1]. An NT-related 6-amino-acid peptide has also been isolated from porcine spinal cord, named neuromedin N (NMN) [2]. NT and NMN have an identical amino acid sequence of Pro-Tyr-Ile-Leu at the C-terminus and are encoded by the same precursor gene [3]. There are 3 types of NT receptors (NTR1, NTR2, and NTR3/sortilin) in mammals [4-7], and NT has the highest affinity to NTR1. NT and NMN are found in the brain and the gastrointestinal tract, where they contribute to a number of functions in mammals. In gastrointestinal tract, NT is involved in digestion, gut motility, intestinal neuroinflammation, and regeneration [8]. In the central nervous system, NT participates in hypothermia, antinociception, dopamine neurotransmission, and anterior pituitary hormone secretion [9]. Furthermore, it has been demonstrated that the central administration of NT reduces food intake in rats [10-12].

In avian species, NT and an NT-related 6-amino-acid

peptide corresponding to mammalian NMN (Lys, Asn, NT⁸⁻¹³; LANT-6) have been purified from chicken intestine [13,14]. NT and LANT-6 also have an identical 4-amino acid sequence at the C-terminus and are encoded by the same precursor gene as in mammals [15]. Figure 1 shows the amino acid sequence of the chicken NT/LANT-6 precursor protein. With regard to the receptors, only NTR1 has been characterized from chicken intestine [16].

We have recently identified NT and LANT-6 in the chicken brain and used *in situ* hybridization to reveal that the NT/LANT-6 precursor mRNA-expressing cells were mainly located in the telencephalon, which contains the nidopallium, hyperpallium, and hippocampus; and the hypothalamic infundibulum, which contains the infundibular nucleus and medial mammillary nucleus [17]. Above all, the hypothalamic infundibulum is known to be involved in regulation of food intake, and the avian infundibular nucleus corresponds to the mammalian arcuate nucleus. For instance, neuropeptide Y (NPY) is an orexigenic peptide expressed in the arcuate nucleus in mammals [18]. In the avian hypothalamus, NPY is expressed in the infundibular nucleus [19] and acts to potently increase food intake [20-22]. As

described above, the central administration of NT inhibits food intake in rats [10-12]. These facts suggest that NT and LANT-6 may also regulate feeding behavior in birds.

In this study, we first quantified the expression of NT/LANT-6 precursor and NTR1 mRNAs in the

hypothalamic infundibulum of the chick brain. Then, we analyzed changes in each mRNA expression during postnatal development and after fasting. Furthermore, effects of NT and LANT-6 on food intake were investigated.

2. Materials and Methods

2.1. Animals

Male layer chicks (*Gallus gallus domesticus*) were purchased from a commercial company (Nihon-Layer, Gifu, Japan).

For molecular biological analysis, chicks were kept in a room at 28°C with continuous lighting and were given food and tap water ad libitum. The experimental protocol was performed in accordance with the Guide for the Care and Use of Laboratory Animals prepared by Hiroshima University (Higashi-Hiroshima, Japan).

For behavioral studies, chicks were kept in a room at 30°C with continuous lighting and were given commercial diet (crumble, crude protein: 24%, metabolizable energy: 3,050 kcal/kg; Toyohashi Feed Mills, Aichi, Japan) and tap water ad libitum. Chicks were placed in individual cages 1 day prior to each experiment. They were weighed and divided into experimental groups as uniformly as possible for each treatment. Chicks were maintained in accordance with the recommendations of the National Research Council [23]. The experimental protocol was approved by the Committee of Animal Care and Use in Ehime University (Ehime, Japan).

2.2. RNA and cDNA Preparation

Chicks were killed by decapitation. The telencephalon, diencephalon, hypothalamic infundibulum, optic tectum, pons and medulla oblongata, and cerebellum were dissected, snap-frozen in liquid nitrogen, and used for RNA isolation. RNA from the chick brain was extracted using a TRIzol reagent or an RNAqueous-Micro kit (Life Technologies, Carlsbad, CA) in accordance with the manufacturer's instructions.

The first strand of cDNA was synthesized from RNA prepared from each brain regions using a ReverTra Ace qPCR RT Kit Master Mix with gDNA Remover (TOYOBO, Osaka, Japan) in accordance with the manufacturer's instructions.

2.3. Real-Time PCR

To analyze the expression levels of NT/LANT-6 precursor

and NTR1 mRNAs, the cDNA prepared from each brain region was amplified. PCR amplifications were carried out with the THUNDERBIRD SYBR qPCR Mix (TOYOBO) using the following program: 95°C for 20 sec, 40 cycles at 95°C for 3 sec, and at 60°C for 30 sec. The PCR products in each cycle were monitored using a real-time thermal cycler (StepOne; Life Technologies). The each level of mRNA expression was normalized to the level of β -actin (ACTB) mRNA. The nucleotide sequences of primers for the amplification are shown in Table 1.

Table 1. Nucleotide sequence of primers.

Target gene	Primer sequences (5' to 3')
NT/LANT-6 precursor	Forward: CATTCTGGAAGACAGTTCC
	Reverse: GCGCTTGCTGAAGTAATC
NTR1	Forward: TTTGCTACGTCCCTCCAAC
	Reverse: ATGGGGTTGATTGCCGAAC
β -actin (ACTB)	Forward: AGCCAACAGAGAGAAGATGA
	Reverse: CCAGAGTCCATCACAATACC

2.4. Peptide Preparation

NT and LANT-6 were synthesized by Fmoc solid-phase peptide synthesis using a peptide synthesizer, Syro Wave (Biotage, Uppsala, Sweden). The peptides were purified by reverse-phase high-performance liquid chromatography (HPLC) using a C18 column (YMC-Pack Pro C18, 10×150 mm; YMC, Kyoto, Japan). The collected peaks were evaporated and lyophilized. Synthetic peptides were confirmed by matrix-assisted laser desorption-ionization time-of-flight mass spectrometry (MALDI-TOF-MS) analysis on AXIMA-CFR plus (Shimadzu, Kyoto, Japan).

The synthetic NT and LANT-6 were dissolved in a saline solution containing 0.1% Evans blue dye, which included 0.005 N HCl to support the dissolution of peptides. This vehicle was used for the control treatment.

2.5. Intracerebroventricular (ICV) Injections

Six-day-old chicks were injected ICV with NT or LANT-6. All injections were given between 8:00 and 10:00 a.m. and performed according to a previously reported method [24]. In brief, the head of the chick was inserted into an acrylic box with a hole in the top plate. The injection coordinates

targeting the left lateral ventricle were 3 mm anterior from the parietal bone, 1 mm lateral from the sagittal suture, and 3 mm deep. Anatomical landmarks were determined visually and by palpation. The peptide solution was injected through the hole using a micro-syringe at a volume of 10 μ l. This procedure is quick and does not stress the neonatal chicks judging from food intake and corticosterone release [25,26]. At the end of each experiment, the chicks were euthanized with an overdose of pentobarbital. The brain was then removed to confirm the accuracy of injection. Any chicks in which Evans blue dye could not be defined in the lateral ventricle were not used for further analyses.

Figure 2. Expression levels of NT/LANT-6 precursor and NTR1 mRNAs in each brain region of 1-day-old chicks ($n = 4-6$). Each value represents mean $\pm$ SEM.

Figure 3. Expression levels of NT/LANT-6 precursor and NTR1 mRNAs in the hypothalamic infundibulum. (A) Changes in the level of mRNA expression during postnatal development ($n = 4-6$). (B) Changes in the level of mRNA expression after a 48 hour fast in 7-day-old chicks ($n = 6-8$). Each value represents mean $\pm$ SEM. An asterisk indicates a statistically significant difference ($P < 0.05$).

2.6. Measurement of Food Intake

Food intake was measured under ad libitum feeding conditions. A pre-weighed feeder was given to each chick, and food intake was measured at 30, 60, and 90 min after the injection using a digital balance with an accuracy of 1 mg.

2.7. Statistical Analysis

Data were analyzed with Student's t-test or two-way analysis of variance (ANOVA) followed by the Tukey-Kramer test as a post hoc test. The significance level was set at $P < 0.05$. All results are expressed as the mean $\pm$ SEM. The numbers of chicks for each experiment are noted in the figure legends.

3. Results

3.1. Expression of NT/LANT-6 Precursor mRNA

The expression levels of NT/LANT-6 precursor and NTR1 mRNAs in the following brain regions of 1-day-old chicks were examined by real-time PCR: the telencephalon, the diencephalon, the hypothalamic infundibulum, the optic tectum, the pons and medulla oblongata, and the cerebellum. The expression level of NT/LANT-6 precursor mRNA was highest in the telencephalon, followed by the hypothalamic infundibulum, and lowest in the cerebellum, whereas the expression level of NTR1 mRNA was highest in the hypothalamic infundibulum and below measurable limits in the cerebellum (Fig. 2).

Furthermore, changes in each mRNA expression in the hypothalamic infundibulum were examined. During postnatal development at days 1, 8, and 15, the expression level of NT/LANT-6 precursor mRNA showed a trend toward increasing (Fig. 3A). In 7-day-old chicks, the NT/LANT-6 precursor mRNA level was increased 2.9-fold after 48-hour fasting (Fig. 3B). On the other hand, the NTR1 mRNA level was not changed in both analyses (Fig. 3)

Figure 4. Effects of ICV injection of NT or LANT-6 on food intake. Six-day-old chicks were injected with NT (A and B) and LANT-6 (C and D) under *ad libitum* feeding (A and C) or 15-hour fasting conditions (B and D), respectively. Each value represents mean $\pm$ SEM ($n = 6-10$).

3.2. Effects of NT and LANT-6 on Food Intake

ICV injection of either NT (Figs. 4A and B) or LANT-6 (Figs. 4C and D) had no effect on food intake under either *ad libitum* feeding (Figs. 4A and C) or 15-hour fasting (Figs. 4B and D) conditions in 6-day-old chicks.

4. Discussion

In the hypothalamic infundibulum, an important region for regulating feeding behaviors, the expression levels of NT/LANT-6 precursor and NTR1 mRNAs were moderately high. Furthermore, the expression level of NT/LANT-6 precursor mRNA was increased 2.9-fold after 48-hour fasting.

Despite the anorexigenic effect of NT in mammals, neither NT nor LANT-6 had an effect on food intake in chicks. It has been reported that the reduction of food intake induced by ICV injection of NT is greater in rats after fasting than after feeding *ad libitum* [12]. However, in chicks NT and LANT-6 had no effect on food intake even under the fasting condition. The required dose of NT to suppress feeding was 2 nmol in rats and 0.1 nmol in mice under fasting conditions [10,27]. In general, most bioactive substances take effect at lower doses in chicks than in rats. Thus, the doses of NT (up to 1 nmol)

and LANT-6 (up to 2 nmol) used in this study would seem to be sufficient. Although we tested a higher dose of LANT-6 (10 nmol) in *ad libitum* feeding conditions since LANT-6 was shown to be 10 times less potent than NT on the colon contraction [17], food intake still did not change (data not shown).

The mechanisms for central regulation of food intake are slightly different between mammals and chicks [28]. For example, growth hormone-releasing hormone (GHRH) facilitates feeding behavior in mammals [29,30] but suppresses feeding in chicks [31]. In contrast, prolactin-releasing peptide (PrRP) suppresses feeding behavior in rats [32,33] but increases feeding in chicks [34]. These results suggest that the effects of NT on food intake in chicks are also different from those observed in mammals.

Leptin is an anorexigenic peptide found in mammals [35]. NT neurons in the hypothalamus express leptin receptors [36], and ICV injection of leptin has been shown to increase gene expression of hypothalamic NT in rats [37]. Furthermore, leptin induced feeding suppression was blocked by prior administration of NT antiserum or NT receptor antagonist in rats [38]. These data suggest that there is a close relationship between leptin and NT in mammals. Recently, leptin has been identified in avian species such as peregrine falcon [39], rock dove [40], and zebra finch [41]. In the chicken, although

leptin has not yet been identified, there are several reports concerning effects of leptin on feeding behavior. Central administration of leptin decreased food intake in 4 or 7 week old chickens [42] but had no effect on feeding in 2-day-old chicks [43]. These results indicated that the responsiveness to the same substance could change with age. Leptin could suppress feeding by acting through NT release, which would explain why it has no effect in chicks. This study showed that the expression level of NT/LANT-6 precursor mRNA in the hypothalamic infundibulum tended to increase during postnatal development. Therefore, it is possible that NT could still decrease food intake in older chickens.

On the other hand, there are several reports suggesting a relationship between NT and histamine. Histamine decreases food intake in rats [44], and the effect is mainly mediated by activation of the histamine H₁ receptor in the brain [45]. Furthermore, the anorexigenic effect of NT is partially blocked by treatment with a H₁ receptor antagonist or by knockout of the H₁ receptor in mice [27]. In chicks, histamine is expressed in the medial mammillary nucleus of the hypothalamic infundibulum [46], and ICV injection of histamine decreases food intake [46,47], whereas in this study NT had no effect on food intake. These results suggest that the relationship between NT and histamine in avian species is different from that observed in mammals.

5. Conclusion

NT/LANT-6 precursor and NTR1 mRNAs were expressed at a moderately high level in the hypothalamic infundibulum. Within this region, the expression level of NT/LANT-6 precursor mRNA showed a trend toward increasing during postnatal development and increased 2.9-fold after 48-hour fast, although NTR1 mRNA level was not changed in both analyses. In contrast to the anorexigenic effect of NT in mammals, ICV injection of NT and LANT-6 had no effect on chick food intake. To develop a better understanding about the effects of NT and LANT-6 on chicken feeding behavior, further study with older chickens will be required.

Acknowledgments

The mass spectrometry was performed using AXIMA-CFR plus at the Natural Science Center for Basic Research and Development (N-BARD), Hiroshima University. This work was supported by MEXT/JSPS KAKENHI grants (22687004 and 26291066 to K.U. and 25440171 to E.I.-U), Grant-in-Aid for JSPS Fellows (to K.M.), the Kieikai Research Foundation (K.U.), and the Program for Promotion of Basic and Applied Researches for Innovations in Bio-oriented Industry (K.U.).
