Abstract: In this paper, a new efficient syndrome-weight decoding algorithm (NESWDA) is presented to decode up to five possible errors in a binary systematic (47, 24, 11) quadratic residue (QR) code. The main idea of NESWDA is based on the property cyclic codes together with the weight of syndrome difference. The advantage of the NESWDA decoding algorithm over the previous table look-up methods is that it has no need of a look-up table to store the syndromes and their corresponding error patterns in the memory. Moreover, it can be extended to decode all five-error-correcting binary QR codes.

Keywords: Cyclic Codes, Decoding, Quadratic Residue Code

1. Introduction

The well-known QR codes, introduced by Prange in his report [1] in 1957, are cyclic BCH codes with code rates greater than or equal to one-half and generally have large minimum distances so that most of the known QR codes are among the best-known codes. The code augmented by a parity bit, for instance, the (24, 12, 8) QR code has been used for numerous communication links, including the Voyager imaging system link of NASA [2]. In the past decades, a series of different decoding methods given in [6-15] have been developed to decode the QR code. However, these algebraic decoding techniques require a large number of complicated computations in a finite field. These complicated computations will lead to a time delay in the decoding procedures and therefore the decoding time will become unrealistic when the code length is large. Therefore, to reduce the decoding complexity, we introduce the NESWDA algorithm, which can be used to decode the (47, 24, 11) QR code. It allows for the correction of up to $t = \lfloor (d - 1)/2 \rfloor = \lfloor (11 - 1)/2 \rfloor = 5$ errors, where $\lfloor x \rfloor$ denotes the greatest integer less than or equal to $x$; $t$ is the error-correcting capability and $d = 11$ is the minimum Hamming distance of the code.

Recently, table look-up decoding algorithms have been developed to decode the (47, 24, 11) QR code. The full lookup table in the conventional table look-up decoding algorithm (CTLDA) needs

$$\sum_{i=1}^{t-1} \binom{47}{i} = 1729647$$

syndromes and their corresponding error patterns. It requires $1729647 \times (6\text{bytes} + 3\text{bytes}) = 14.85$ Mbytes memory size to store the table. Such a large memory required makes the computation very complicated. An efficient algorithm named look-up table decoding (LTD) algorithm in [3] to decode the (47, 24, 11) QR code needs 1.05 Mbytes memory size to store the table. The well-known syndrome decoder [2]

Requires

$$\left( \sum_{i=1}^{t} \binom{47}{i} \right)/47 = 1729647/47 = 36801$$

syndromes corresponding to error patterns stored in a table with a 36801 × (6bytes +3bytes)=1024 ≈ 323.45 Kbytes memory size, called the reduced lookup table (RLT). However, this memory size of the RLT is still so large that one needs to further reduce the memory size of the look-up table. To achieve this end, an efficient table look-up decoding algorithm (TLDA) in [4] is developed to decode the (47, 24, 11) QR code, the memory size of the developed condensed look-up table consists of 36.6 Kbytes, and Lin et al. [5] used a novel table look-up decoding algorithm, called the cyclic weight (CW) decoding algorithm, together with a memory size 20.43 Kbytes memory size to decode the (47, 24, 11) QR code. As shown in this paper, the proposed NESWDA does not need a memory size to store the look-up table. The prime idea of the proposed
The binary QR codes are a nice family of linear cyclic codes. Let \((n,k,d)\) or \((n,(n+1)/2,d)\) denote the binary QR codes with generator polynomial \(g(x)\) over \(GF(2)\). The length of this code is a prime number of the form \(n = 8l + 1\), where \(l\) is some integer. Also, let \(k = (n+1)/2\) denote the message length or information length, and \(d\) denote the minimum Hamming distance of the code. The set \(Q_n\) of quadratic residues modulo \(n\) is the set of nonzero squares modulo \(n\); that is, \(Q_n = \{j | j \equiv x^2 \mod n, 1 \leq x \leq n-1\}\). If \(n = 47\), then its quadratic residue set is then the element \(\beta = \alpha^u\) where \(u = (2^{23} - 1)/47 = 178\), 481, is a primitive 47th root of unity in \(GF(2^{23})\). The generator polynomial \(g(x)\) of the binary \((47, 24, 11)\) QR code is defined by

\[
H^T = \begin{bmatrix}
  A \\
  I_{n-k}
\end{bmatrix} = \begin{bmatrix}
  h_0 \\
  h_1 \\
  \vdots \\
  h_{n-k-1}
\end{bmatrix}
\]

For \(C_{47}\), \(A\) has the following form:

\[
\begin{bmatrix}
  1 & 1 & 1 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 1 & 1 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 \\
  0 & 1 & 1 & 1 & 0 & 1 & 1 & 1 & 0 & 1 & 0 & 1 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 0 & 0 & 0 & 1 & 1 \\
  0 & 0 & 0 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 1 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 1 & 0 & 0 & 0 & 1 & 1 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 1 & 0 & 0 & 0 & 1 & 1 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 1 & 0 & 1 & 1 & 1 & 0 & 1 & 0 & 0 & 0 & 1 & 1 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 1 & 1 & 0 & 1 & 0 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 1 & 1 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 1 & 1 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 1 & 1 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 1 & 1 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 1 & 1 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 1 & 1 & 1 & 1 & 0 & 1 & 1 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 1 & 1 & 1 & 1 & 0 & 1 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 1 & 1 & 1 & 1 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 1 & 1 & 1 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 1 & 1 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 1 & 0 & 1 & 1 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 1 & 0 & 1 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 1 & 0 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 1 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 0 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
  0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
\end{bmatrix}
\]

Figure 1. \(A\) of \(C_{47}\).

3. Decoding Algorithm and Theorems

Definition 1. The Hamming weight of a binary vector \(a\) is denoted by \(w(a)\), and the Hamming distance between \(a\) and \(b\)
is denoted by \( d(a, b) = w(a + b) \).

**Theorem 1.** Let \( a = (a_0, a_1, \ldots, a_{n-1}) \) and \( b = (b_0, b_1, \ldots, b_{n-1}) \) be two binary vectors, then

\[
\begin{align*}
  w(a+b) &= w(a) + w(b) + 2 \sum_{j=0}^{n-1} a_j b_j. \\
\end{align*}
\]

**Corollary 1.** If \( a_j = 0 \) for \( 0 \leq j \leq n-1 \), then

\[
  w(a+b) = w(a) + w(b). 
\]

The following theorem is useful to compute the syndrome of the received word when the received word shifts one bit to the right.

**Theorem 2.** Let \( s(x) \) be the syndrome polynomial corresponding to a received polynomial \( r(x) \). Also, let \( r^{(i)}(x) \) be the polynomial obtained by cyclically shifting the coefficients of \( r(x) \) one bit to the right. Then the remainder obtained when dividing \( xs(x) \) by \( g(x) \) is the syndrome \( s^{(i)}(x) \) corresponding to \( r^{(i)}(x) \).

For a detailed proof, see [2].

However, if the syndrome cyclically shifts many times, then the syndrome computation is quite time-consuming for dividing \( xs(x) \) by \( g(x) \) many times. The following theorem provides an efficient method to compute \( s^{(i)}(x) \) for \( 0 \leq i \leq n-1 \), and it can save a lot of computational time.

**Theorem 3.** For the binary QR codes, let \( r_j \) be an element of \( r \) and \( h_j \) be the \( j \)th row vector of \( H^T \) for \( 0 \leq j \leq n-1 \). Then the syndrome \( s^{(i)}(x) \) of \( r^{(i)}(x) \) for \( 0 \leq i \leq n-1 \) has the form

\[
  s^{(i)} = \sum_{j=0}^{n-1} r_j h_{i+j},
\]

where the suffix \( [x] \) of \( h \) denotes \( x \) mod \( n \).

**Proof.** Let \( r = (r_0, r_1, \ldots, r_{n-1}) \) and \( r^{(i)} = (r_{n-i}, \ldots, r_{n-1}, r_0, \ldots, r_{n-i-1}) \) for \( 0 \leq i \leq n-1 \). We have

\[
  s^{(i)} = s_{r_0 h_{i+0}} + \ldots + s_{r_{n-i} h_{i+n-i-1}} = \sum_{j=0}^{n-1} r_j h_{i+j}
\]

The proof is thus completed.

Theorem 3 reveals that the syndrome of \( r^{(i)}(x) \) can be fast computed by the vector addition. Theorem 4 also provides an efficient method to simplify the decoding step by using the syndrome weight.

**Theorem 4.** For the binary QR codes, it is assumed that there are \( v \) errors in the received word, where \( 1 \leq v \leq t \) and \( t = \lfloor (d-1)/2 \rfloor \). All \( v \) errors are in the parity-check bits if and only if the weight of syndrome \( w(s) = v \).

For a detailed proof, see [4].

**Theorem 5.** For the binary QR codes, if \( v \) errors are in the information bits of the received word, where \( 1 \leq v \leq t \) and \( t = \lfloor (d-1)/2 \rfloor \), then the weight of the corresponding syndrome vector satisfies

\[
  w(s) \geq d - v + t + 1
\]

For a detailed proof, see [5].

**Theorem 6.** For the binary QR codes, let \( e_1 = (e_0, e_1, \ldots, e_{n-1}) \) be an error pattern and \( e_n = (e_0, \ldots, e_{n-1}) \), \( e_p = (e_1, \ldots, e_{n-1}) \) be respectively its message section and parity check section. Assume that \( w(e_n) \geq 1 \), \( w(e_p) \geq 1 \) and \( w(e) \leq t \), where \( t = \lfloor (d-1)/2 \rfloor \), then the weight of the corresponding syndrome vector satisfies

\[
  w(s) \geq t + 1.
\]

**Proof.** As \( w(s) = w(e H^T) \)

\[
  = w\left(e_0, 0_{(n-1)}\right) H^T + w(e_1, e_n) H^T
  \geq (d - w(e_n)) - w(e_p)
  \geq d - w(e_n) + w(e_p)
  \geq d-t + 1
\]

the proof is thus completed.

Given a received word \( r \), the syndrome \( s^{(i)}(r) \) of \( r^{(i)} \) can be fast computed by theorem 3. According to theorem 4, if \( 1 \leq w(s) \leq 5 \) then error positions are in the parity-check bits of \( r \). If \( 1 \leq w(s^{(i)}) \leq 5 \), then the error positions are in the information bits of \( r \). Let \( h_j \) denote the \( j \)th row vector of \( H^T \), where \( 0 \leq j \leq n-1 \). Also let \( s_{d_j} \) denote the syndrome difference between the syndromes of \( r \) and \( h_j \) in each decoding step \( z \). By using the weight of \( s_{d_j} \), the error cases can be quickly determined. Let \( u_0 = (1, 0, \ldots, 0) \) be a \( k \)-tuples unit vector and \( u_i \) has only one nonzero component at the \( i \)th position, where \( 0 \leq i \leq k-1 \). By using these properties the decoding algorithm can be constructed. Let case I, C, P denote the error position in the information bits, center bit, and parity-check bits of \( r \), respectively. The decoding steps of the proposed NESWDA work as follows:

(1) (No error, P, PP, PPP, and PPPPP cases) By theorem 3, compute \( s \) and \( w(s) \). If \( 0 \leq w(s) \leq 5 \), then the information vector is \( m = (r_0, r_1, \ldots, r_{n-1}) \). Go to step (8).

(2) (I, II, III, IIII, and IIIII cases) By theorem 3, compute \( s^{(i)} \) and \( w(s^{(i)}) \). If \( 1 \leq w(s^{(i)}) \leq 5 \), then the corrected
information vector is \[ m = (r_0, r_1, \ldots, r_{k-1}) + \left( s^{(k)} - h_i \right) \]. Go to step (8).

(3) (IP, IPP, IPPP, C, CP, CPP, CPPP, and CPPPP cases) Compute the syndrome difference \[ s_d = s - h_i \] for \( 0 \leq i \leq k - 1 \) and \( w(s_d) \). If \( w(s_d) \leq 4 \), then the corrected information vector \[ m = (r_0, r_1, \ldots, r_{k-1}) + u_i \]. Go to step (8).

(4) (IC, IIC, IIIIC, IIP, IIIP, and IIIIP cases) Compute the syndrome difference \[ s_d = s^{(k)} - h_i \] for \( 0 \leq i \leq k - 1 \) and \( w(s_d) \). If \( w(s_d) \leq 4 \) and \( i = 0 \), then the corrected information vector \[ m = (r_0, r_1, \ldots, r_{k-1}) + u_0 + (s_d, 0) \]. Go to step (8). If \( w(s_d) \leq 4 \) and \( 0 \leq i < k - 1 \), then the corrected information vector \[ m = (r_0, r_1, \ldots, r_{k-1}) + (s_d, 0) \]. Go to step (8).

(5) (IIPP, IPPPP, IC, ICPP, and ICPPP cases) Compute the syndrome difference \[ s_d = s - h_i \] for \( 0 \leq i \leq j \leq k - 1 \) and \( w(s_d) \). If \( w(s_d) \leq 3 \), then the corrected information vector \[ m = (r_0, r_1, \ldots, r_{k-1}) + u_i + u_j \]. Go to step (8).

(6) (ICP, IICP, and ICPP cases) Compute the syndrome difference \[ s_d = s^{(i)} - h_i \] for \( 0 \leq i < j \leq k - 1 \) and \( w(s_d) \). If \( w(s_d) \leq 3 \) and \( i = 0 \), then the corrected information vector \[ m = (r_0, r_1, \ldots, r_{k-1}) + u_{k+1} + (s_d, 0) \]. If \( w(s_d) \leq 3 \) and \( i > 0 \), then the corrected information vector \[ m = (r_0, r_1, \ldots, r_{k-1}) + (s_d, 0) \]. Go to step (8).

(7) (ICPP case) Compute the syndrome difference \[ s_d = s - h_{k-1} - h_i \] for \( 0 \leq i \leq j \leq k - 2 \) and \( w(s_d) \). If \( w(s_d) \leq 2 \), then the corrected information vector \[ m = (r_0, r_1, \ldots, r_{k-1}) + u_i + u_j + u_{k+1} \]. Go to step (8).

(8) Stop.

Table 1 lists all the 35 error cases and the number of error patterns in each decoding step of \( C_{47} \) of the proposed NESWDA. The flowchart of the proposed NESWDA is shown in figure 1.

Table 1. The number of error patterns in each decoding step of \( C_{47} \).

4. Example

In this section, two examples are presented to illustrate the proposed NESWDA.

Example 1. Let a information \( m = (010000000000000000000000) \) be encoded into a \( C_{47} \) codeword \( c = (01000000000000000000000000000000000000000000000) \). If the received word \( r = (111100000000000000000001111011101110001100) \), then the error pattern \( e = (10110000000000000000000000000000000000000000000) \), which means a III error case. The decoding procedure is composed of the following steps.

(1) Compute \( s = (11010100010110000111101110001110111011101110001100) \) and \( w(s) = 12 \). Since \( w(s) > 5 \), go to step 2.

(2) Compute \( s^{24} = (10110000000000000000000000000000000000000000000) \) and \( w(s^{24}) = 3 \leq 5 \). The corrected information vector is

\[
(11110000000000000000000000000000000000000000000) + (10110000000000000000000000000000000000000000000)
= (01000000000000000000000000000000000000000000000).
\]

Go to stop.
Figure 2. Flowchart of the proposed NESWDA.
Example 2. Let a information \( m = (010000000000000000000000011110110110110001100) \) be encoded into a \( C_{47} \) codeword \( c = (010000000000000000000000011110111101101110001100) \).

If the received word \( r = (01111000000000000000000100111011101101110001100) \),
then the error pattern \( e = (00110000000000000000000101000000000000000000000000) \), which means a IICP case. The decoding procedure is composed of the following steps.

(1) Compute \( s = (10000101110111100000010000100100) \) and \( w(s) = 9 > 5 \), go to step 2.

(2) Compute \( s^{24} = (111110101101011101111) \) and \( w(s^{24}) = 16 > 5 \), go to step 3.

(3) Compute \( s_d = s - h \) for \( 0 \leq i \leq 23 \) and \( w(s_d) \).

\[
\begin{align*}
s_d & = s - h_0 = (100001011101110100001000) - (11111011110111110001100) \\
& = (011110101000010001111100), \quad w(s_d) = 9. \\
\end{align*}
\]

\[
\begin{align*}
s_d & = s - h_1 = (1000010111011110100001000) - (01111101101011110001100) \\
& = (111111010111011010001001), \quad w(s_d) = 13. \\
\end{align*}
\]

\[
\begin{align*}
s_d & = s - h_2 = (1000010111011111000001000) - (10001001111101000100110) \\
& = (000000011000010101001101), \quad w(s_d) = 5. \\
\end{align*}
\]

\[
\begin{align*}
s_d & = s - h_3 = (1000010111011111100001000) - (11010001111110100101101) \\
& = (011000001111001001010011), \quad w(s_d) = 11. \\
\end{align*}
\]

Since every \( w(s_d) > 4 \), go to step 4.

(4) Compute \( s_d = s^{24} - h \) for \( 0 \leq i \leq 23 \) and \( w(s_d) \).

\[
\begin{align*}
s_d & = s^{24} - h_0 = (111110101101011101111) - (11111101110111110001100) \\
& = (000011011101101100110110), \quad w(s_d) = 12. \\
\end{align*}
\]

\[
\begin{align*}
s_d & = s^{24} - h_1 = (11111101110111110001100) - (01111011011101110001100) \\
& = (1000000011000000011111111111111111), \quad w(s_d) = 14. \\
\end{align*}
\]

Since every \( w(s_d) > 4 \), go to step 5.

(5) Compute \( s_d = s - h_i - h_j \) for \( 0 \leq i < j \leq 23 \) and \( w(s_d) \).

\[
\begin{align*}
s_d & = s - h_0 - h_1 = (0000100111001001100001000) - (101000101111011111000001) \\
& = (000000011000010101001011), \quad w(s_d) = 6. \\
\end{align*}
\]

\[
\begin{align*}
s_d & = s - h_0 - h_2 = (0000100111001001100001000) - (110000111100000001100001) \\
& = (000000011000010101001011), \quad w(s_d) = 15. \\
\end{align*}
\]

\[
\begin{align*}
s_d & = s - h_0 - h_3 = (0000100111001001100001000) - (110000111100000001100001) \\
& = (000000011000010101001011), \quad w(s_d) = 11. \\
\end{align*}
\]

\[
\begin{align*}
s_d & = s - h_1 - h_2 = (0000111101011000011111111111111111), \quad w(s_d) = 11. \\
\end{align*}
\]

Since every \( w(s_d) > 3 \), go to step 6.

(6) Compute \( s_d = s^{24} - h_i - h_j \) for \( 0 \leq i < j \leq 23 \) and \( w(s_d) \).

\[
\begin{align*}
s_d & = s^{24} - h_0 - h_1 = (11111011101110110001100) - (01111011111101110001100) \\
& = (1000000011000000011111111111111111), \quad w(s_d) = 12. \\
\end{align*}
\]

\[
\begin{align*}
s_d & = s^{24} - h_i - h_j = (0000110111101001100001100) - (0111101111011101110001100) \\
& = (0110000011010001100001100), \quad w(s_d) = 2. \\
\end{align*}
\]

Since \( w(s_d) = 2 \leq 3 \), and \( i = 0 \). The corrected information...
\[ m = (r_0, r_1, \ldots, r_{23}) + u_0 + (sd_0, 0) = \\
(01110000000000000000000001) + \\
(0000000000000000000000000001) + \\
(0011000000000000000000000000) \\
= (0100000000000000000000000000). \]

Go to stop.

5. Conclusions

A new NESWDA decoding algorithm is developed to correct up to five errors for the approximate half-rate (47, 24, 11) QR code. The main idea behind the proposed NESWDA is based on the fact that it makes use of the properties of cyclic codes, the weight of syndrome difference. The proposed NESWDA has no need of a look-up table to store the syndromes and their corresponding error patterns in the memory. Moreover, it can be extended to decode all five-error-correcting binary QR codes.
