Abstract: The principles of controlling an AC driven three phase induction motor employing constant volts/hertz (v/f) control method and the space vector pulse width modulation (SVPWM) technique are reviewed. The induction motor is one of the most common electrical motors in usage, owing to its unique characteristics. Its further application strength requires a robust, problem handling, fast and intelligent speed control system. As a result of this, developing an intelligent knowledge based fuzzy logic controller (FLC) became eminent, and on this basis, this paper is presented. By varying the motor speed with input reference speed, an error signal and a feedback loop is generated. The FLC then operates on the principles of mapping with corrective measure of an error signal generated and it is regulated by sets of programmable IF-THEN rules integrating the Mamdani fuzzy inference approach. The rules projected and formed are used to overcome drawbacks such as complexities and insensitivities to changes in model parameters associated to conventional controllers. The application of the constant v/f method was used to maintain constant voltage to frequency ratio, therefore, creating a constant magnetic field and a maximum torque throughout the operating range. This in turn generates a voltage and an angle command for the actualization of the SVPWM technique. This entire set up was repeated but now with a classical control method like the proportional integral differential (PID) controller. With a simulation time of 2s, results showed that with FLC, a better speed response can be achieved from a 5Hp 350V 50Hz AC motor attaining steady-state at 0.21s at no-load conditions. Simulation results showed a superior dynamic scheme of the FLC over the PI controller in terms of sensitivity to changes in model parameters. With a load torque of 10Nm applied at 1s, the FLC achieved stability at 1.2s still maintaining a constant speed of 157rads/s.

Keywords: Three Phase AC Induction Motor Drive, Scalar Closed Loop, Fuzzy Logic Approach, SVPWM Technique

1. Introduction

Asynchronous motor otherwise called induction motor is known as one of the most commonly used electrical motor. It involves speed rotation of the magnetic field, in a rotary machine. It also depends upon the frequency and the number of poles of the machine. It is classified into two types namely; single and three-phase induction motor. An adjustable frequency alternating current (AC) drive system consists of an ordinary three-phase induction motor (IM), an adjustable frequency drive for speed control of the motor and an operators control station. The operator control station provides the operator with the necessary control information

for starting and braking of the motor and also on varying the motor's speed.

The PID controller would have being an effective controller for not just speed control alone, if not for some complexities involved in individually controlling its respective controllers such as proportional, integral and derivative, and summing up their contributions to effectively yield controlled signal output. Also, for its insensitivity to changes made to model parameters which may be as a result of misrepresentation of some control variables. Therefore, the quest and concept of overcoming these drawbacks becomes eminent.

From the problems associated with classical controllers,

there was a need to know how such individual control difficulties be effectively managed or totally substituted with a much more straight forward controller such as a fuzzy logic oriented one? Also, how can all the parameters involved in the control process be mathematically represented and dealt with to accommodate any form of changes made in their regards during operational periods to avoid any form of misrepresentation and insensitivity? In the same light, since this process is representing a closed loop or feedback loop, the question will then be its importance to the control process. With advancements in solid state power devices and microprocessors, variable speed induction motors powered by switching converters are increasingly recorded. These converters have the capability to regulate easily both the frequency and magnitude of the applied voltage and current to a given motor. This results to higher performance and efficiency. One of the common principles of this kind is known as the constant volts/hertz principle which concentrates mainly on varying the magnitude and frequency of the applied voltage to the stator winding, thereby maintaining a constant v/f ratio. In so doing, the magnitude of the magnetic field is kept constant, thus, maintaining a constant maximum torque throughout the operating range. There are various classifications of the adjustable frequency AC drive based on the energy it delivers to a motor [5].

The PWM drive is employed because modulation is achieved by switching the states of the inverter and calculating the appropriate time period for each state. These achievements are possible due to the space vector transformation signals applied to the gates of the power transistors. PWM signals are pulse train with fixed frequency and magnitude plus variable pulse width. During the on and off intervals of the transistor, the PWM signal changes from one period to another as a result of its introduction to the gates [11]. In this control technique, the frequency of the PWM signal must be higher than the modulating signal, which is the fundamental frequency, in a way that the energy delivered to the motor and its load depends mostly on the modulating signal.

2. Method

In the industry today, amongst other types of machines, induction motors especially the squirrel cage has gained more popularity in terms of its numerous advantages ranging from its rugged construction and lower cost of maintenance to its reliability and better performance results etc. There are a host of methods available for speed control of this type of induction motor which includes; v/f control, field oriented control, flux vector control, sensor less vector control etc, but the v/f control method happens to be common and simple to implement. This is because it takes speed reference command from an external source and varies it with the existing motor speed. This in turn creates a feedback loop and an error signal that is corrected by established rules incorporated in the fuzzy logic controller to generate a control signal used by other blocks to achieve the objectives of the control process.

By varying the voltage and frequency supply of the connected motor, the v/f control resultant are voltage magnitude and phase angle command for the realization of the SVPWM scheme which was adopted and used to obtain variable voltage and frequency from the voltage source inverter (VSI). This is then utilized by the connected three phase induction motor.

[1] Presented a pulse width modulated AC drive technique. This review dealt with power conversion unit, PWM generation and its applications to the various types of control of AC drives including the v/f control technique. [3] Presented a design model employing a Takagi-Sugeno fuzzy logic control scheme for controlling some of the parameters such as speed, torque, flux, voltage etc of an IM. Fuzzy logic based controllers were considered and a proposed rule based approach was presented. [4] Presented an intelligent and advanced speed control based on fuzzy logic technique to achieve maximum torque and efficiency. A rule based Mamdani type fuzzy logic controller was applied to a closed loop IM model. Scalar control method was used for controlling speed and a conventional PID was compared using MATLAB/SIMULINK. [6] Presented a v/f control of IM with different pulse width modulation techniques such as sine triangle pulse width modulation, third harmonic pulse width modulation (THPWM) and SVPWM using MATLAB/SIMULINK. The IM was modeled in the synchronous d-q reference frame. The performance of the IM on full load torque is compared using these techniques for third harmonic distortion, harmonic spectra, utilization of DC supply voltage, fundamental peak of the output voltage and motor speed. Results showed the superiority of SVPWM in performance characteristics. [2] Presented a comparative study of speed control of IM using PI and FLC. The IM was modeled using the d-q axis. The v/f control method was employed and a reference speed was set as the control architecture, which included a rule base of 49 rules. With regards to the FLC, these rules portray a nonchalant relationship between the two inputs which are speed error and its derivative and an output which is the change in control. [7] presented a rule-based FLC this was developed for speed control of a three-phase drive in a non-linear system. Speed control application was tested by conducting simulations under different operating conditions employing a constant v/f control scheme and SVPWM technique. The SVPWM was primarily used to generate gate signals for a three-phase two level inverter.

2.2. The Fuzzy Logic Controller (FLC)

The FLC is an intelligent controller that when well programmed, tends to emulate the thoughts of a human operator. As a means of a control law, it is described by a knowledge-based system consisting of IF-THEN rules with vague predicates and a fuzzy logic inference mechanism. The rule base is the main part of the FLC and it is formed by a

family of logical rules that define the relationship between the two inputs (e and δ_e) and an output (w_{sl}) of the controller. Therefore, its difference with the conventional controllers like the PID does not just lie in the type of logic, which can be Boolean or fuzzy, but in the intelligence and aspirations it renders through implementing human understanding in the control algorithm.

A typical FLC is defined by the relationship between change of control and the change in error at a given time (t) is expressed as;

$$w_{sl} = f(e(t), \delta_e(t)) \quad (1)$$

$$\delta_e(t) = e(t) - e(t-1) \quad (2)$$

There are various steps taken when developing an intelligent controller based on fuzzy logic approach. They are;

- Determining the process through the services of an expert operator and subsequently defining respective linguistic variables.
- Determining fuzzy sets through mapping.
- Constructing fuzzy rules covering the whole universe of discourse.
- Encoding fuzzy sets, rules and procedures to perform fuzzy inference into the expert system.
- System evaluation and tuning, if necessary, to meet desired results.

2.3. The Volt/Hertz Block

Assuming the voltage applied to a three-phase IM is sinusoidal, neglecting the stator voltage drop which is hardly 10% of the supplied voltage, then, at steady state, the terminal voltage V is proportional to $\omega\phi$.

Mathematically,

$$V^* \approx j\omega\phi^* \quad (3)$$

$$V \approx \omega\phi; (\omega = 2\pi f) \quad (4)$$

V^* and ϕ^* are the phasors of the stator voltage and flux while V and ϕ are their respective magnitudes (Zhenyu and

David 1998).

$$\phi \approx \frac{V}{\omega} = \frac{V}{2\pi f} = \frac{1}{2\pi} * \frac{V}{f} \quad (5)$$

From equation 5, it follows that if the v/f ratio remains constant with changes in f , then, ϕ remains constant too, leaving the torque independent on the supply frequency. In an ideal situation, the ratio between the magnitude and frequency of the stator voltage is usually based on the rated values of these variables or on the motor rating.

2.4. The SVPWM Generator Block

The space vector modulation is an addition to the primary PWM technique in the sense that it treats the inverter as a single unit. It is used for the creation of AC waveforms most common to three-phase AC powered motors at varying speeds from DC source using class D amplifiers. The inverter can be driven to eight unique states as a result of its switching vectors. The objective of the unique states is to generate PWM load line voltage that are averagely equal to a given or reference load line voltage. The objective is realized from each sampling period by properly selecting the switch states of the inverter and also calculating the appropriate time period for each state [6]. All these are realized by the space vector transformation technique.

The steps involved in achieving the state vector PWM technique can be implemented as follows [8]:

- Determining V_d , V_q , V_{ref} and phase angle α
- Then the time duration T_1 , T_2 and T_0 during switching should be determined
- Lastly, determining the switching time of each transistor from switches S1 through S6.

2.5. Block Diagram for Speed Control of Induction Motor

The block diagram employing the speed control of induction motor is represented in figure 1. It depicts a scalar mode representation. The frequency and supplied voltage of the IM are varied such that it operates at steady state and at the desired speed. For scalar mode representation, both input and output commands are speed, unlike the vector control, where it is torque, flux and reference current respectively.

Figure 1. Block Diagram of a Volts/Hertz IM control with FLC Architecture.

Table 1. Parameters used in the 3- ϕ Induction Motor.

Asynchronous Motor (Mask)	
Induction Motor Rating	[5Hp, 350v, 50Hz]
Preset Model	No
Mechanical Load	Torque T_m [10Nm]
Rotor Type	Squirrel Cage
Reference Frame	Stationary
Nominal Parameters	[5*746, 350, 50]
Stator Resistance /Inductance	[1.115 0.005974]
Rotor Resistance /Inductance	[1.083 0.005974]
Magnetizing Inductance L_m	0.2037
Mechanical	[0.02 0.005752 2]
Initial Conditions	[1,0, 0,0,0, 0,0,0]
Unit	SI
T_s Block	-1
Iterative Model	Trapezoidal non-iterative
Number of Poles	2
Base Frequency	$2*\pi*50$

Table 2. Parameters used in the PID Controller.

PI Controller (Mask)	
Proportional Constant	1
Integral Constant	-1
Derivative constant	0
Filter coefficient	100

Table 3. Parameters used in the IGBT Inverter.

IGBT Inverter, universal bridge (Mask)	
Arms	3
Snubber Resistance	50
Snubber Capacitance	1e-6
Device	IGBT/Diodes
Ron	0.2e-3
Forward Voltages	[2 1]
IGBT Parameters	[1e-6 2e-6]
Dc Voltage Source (Mask)	Source DC Voltage
Amplitude	300V
Measurements	All voltages and currents

3.1. Simulation Results

The results of simulating the IM model in SIMULINK of figure 2 for both FLC and PID controllers with no-load and load conditions are shown in figure 3 through 8. From the simulation results obtained, comparisons were made and their differences noted and adequately explained.

4. Discussion

The time of simulation was set at 2s. At the end of simulation, the scope represented in figure 3 shows the behavior of the controlled variables such as the respective Iabc stator currents, rotor speed and electromagnetic torque for no-load and load conditions, using PID controller. From the plot in figure 3, the IM draws a current of 90A during start-up with a starting torque oscillating around 157Nm, having started from rest or zero speed. Similarly, the rotor speed increased marginally with regards to the starting torque until it reached a breakdown torque of 50Nm at 0.05s. Afterwards, it reached and maintained a constant value of 0Nm at 0.21s. This signifies a no-load condition, until it is acted upon by an applied torque value. At constant torque of 0Nm, the rotor speed attained a steady-state of 157rad/s at 0.15s and maintains that till the end of the simulation.

Similarly, slightly different observations were recorded from figure 4 which represents the control employing the FLC. Comparing figures 3 and 4, at the time of 1s when a load torque of 10Nm was applied, the electromagnetic torque is noticed to have oscillated from the no-load condition, to the tune of the applied torque in figure 4 whereas in figure 3, no action was indicated to this effect. This also had corresponding effects on the rotor speed, the Iabc stator currents and its multiplexed form as in figure 6.

The distinction between the both controllers used, heaps praises on the FLC, owing to its sensitivity, effectiveness and efficiency in handling changes in model parameters. The authenticity of using a very well programmed FLC for speed control, especially in IM, can be verified from the quality of the output signal of the FLC, v/f control and the pulse it delivers to the motor as in figure 7, while 8 and 9 as compared to figures 10 and 11 respectively. This does not discredit the abilities of the PID controller especially in speed control, but provides a better and more reliable alternative to achieving satisfactory speed control response.

5. Conclusion

This paper presents an FLC used for controlling the speed of three-phase induction motor using a closed loop scalar approach. The entire closed loop speed control process is modeled and simulated using MATLAB/SIMULINK software. As a result of drawbacks peculiar to conventional controllers such as the complexities arising from individually controlling its respective controllers like proportional, integral and derivative and summing up their individual contributions to effectively yield controlled signal output. And also, for its insensitivity to changes made to model parameters which may be as a result of misrepresentation of some controller variables, creates the platform on which this paper is presented. With reference to speed and feedback, the FLC produces the proper control signal necessary for the various blocks to play their part in the whole control speed process of the connected motor. With confirmation from simulation results presented in the course of this paper, the

FLC was able to address the problems raised by adequately managing cases of complexities, misrepresentation and insensitivity. This becomes an affirmation that the fuzzy logic approach is feasible and can be an interesting alternative to conventional control even when the system model is known. The controller gives maximum torque over the entire speed range. Therefore, in steady-state, the efficiency of the induction motor is also increased. In conclusion, the fuzzy logic controller shows fast response, smooth performance and high dynamic response with changing and transient conditions.
