Abstract: In this article questions of active clearing of vibrations of system are considered. The paper deals with the active damping of the system's oscillations. Considering that the system is constrained by servosvyazami, for a single-mass system it is proposed to perform servosviaz by changing the mass of the absorber. For this it is proposed to build a digital tracking system.

Keywords: Active Dynamic Damping, Oscillation, Amplitude, Frequency, Extinction, Servo-constraint

1. Introduction

In analytical dynamics the concept about the servo-constraints has been introduced by A. Beghen for the first time. The methods used by A. Beghen have gained the further development in P. Appel, A. Pshcheborsky, V. S. Novoselov, M. F. Shulgin, V. V. Rummyantsev, V. I. Kirgetov, G. K. Pozharitsky's works, Do Shane, A. G. Azizov and others. In these researches much attention has been paid to generalization of the basic principles of dynamics on systems from a servo-constraints, to drawing up the equations of the motion, definition of reactions of mechanics servo-constraints proceeding from the general principles, and, a long time for servo-constraints the model of not releasing non ideal communications was accepted.

Distribution of methods of analytical mechanics on systems from servo-constraints was based mainly on the accounting of the features connected with not ideality servo-constraints, which is shown that for such systems, elementary work of forces of reactions of servo-constraints on the possible motions allowed by communications isn't equal to zero.

Despite importance of a research of the specified feature servo-constraints, annexes of methods of analytical dynamics to a wide range of specific objectives demand the account and other features connected with steady realization servo-constraints. Sh. S. Nugmanova's attention has been for the first time drawn to this circumstance. Being guided by the theory of parametrical release, and the theory of the compelled motions of the N. G. Chetayev's, A. G. Azizov has constructed

the theory allowing to broaden the area of practical applicability of methods of analytical mechanics of system from a servo-constraints, including questions of their steady realization. The theory of creation of systems of the program motion created generally by works of A. S. Galiullin and his followers is close to systems from a servo-constraints.

Still A. Beghen noted that servo-constraints carried out not by means of simple contact, not passively, their realization is connected with use of different forces (electromagnetic, pressure of compressed air, etc.). Questions of realization servo-constraints were considered in Ya. N. Roytenberg, Ya. L. Lunts, V. V. Kozlov, A. G. Azizov, A. Akmukhammedov, R. M. Ziyatdinov's works and others. However, in these researches were considered or special cases, or at realization of servo-constraints ways of her realization weren't considered. Therefore, development of a method of realization of servo-constraints represents both theoretical, and practical interest.

To date, the dynamics of systems with servo- constraints devoted a significant number of studies. These include the works of A. Beghen [2], V. V. Rumiantsev [3], A. G. Azizov [4, 5, 7] and others. In recent years, the theory of systems with servo- constraints began to be developed taking into account the release and the need for a sustainable implementation of the ratio of servo - constraints. These questions are reflected in a number of works of A. G. Azizov [4, 5, 7], based on the theory of parametric liberation, and the theory of forced motions [12].

A. G. Azizov [4, 5, 7] proposed an important constructive method for applications of finding the structure of reaction

bonding forces, which ensures the stabilization of the system's motion relative to the variety determined by servo-constraints.

To systems with servo-constraints the theory of construction of systems of program motion [5] is close, created basically by works of A. S. Galiullin and his pupils.

In this paper, the question of the steady implementation of servo-constraints to a mechanical system with a dynamic absorber is considered.

It is known [1; 2] that additional sources of energy are used to implement servo-connections. These energies can be either external or internal. However, according to A. Begen, «... it is impossible to distract from the way of implementing servo-constraints» [2]. Therefore, the implementation of servo-constraints using dynamic absorbers is considered.

2. Formulation of the Problem

We consider cargo strengthened on a spring with rigidity C_1 , which makes forced oscillations under the action of a disturbing force

$$Q = Q_0 \cdot \sin pt,$$

acting on the object, or by vibrations of the foundation, according to law

$$x_0(t) = x_0 \sin pt,$$

where x_0, Q_0 - amplitudes; p - frequency; t - time.

Under the influence of the enclosed indignation, the object makes one-dimensional vibrations with amplitude [1]:

$$a = \frac{Q_0}{C_1 \left[1 - \left(\frac{\omega}{\omega_0} \right)^2 \right]}$$

where $\omega_0 = \sqrt{\frac{c_1}{m}}$ - own frequency of object. At $\omega \rightarrow \omega_0$

vibration of object essentially increase. It is required to define, under what conditions it is possible to extinguish these vibrations, having attached to cargo 1 on a spring with factor of rigidity C_1 and viscous damper with viscosity factor b_Γ in cargo in 2 weight m_Γ . It means that, on system « Cargo - absorber » one is imposed servo-constraint [2]:

$$x = 0 \quad (1)$$

3. Formulation of the Equations of Motion and Determination of the Reaction Force

As servo-constraint's force operates on absorber, (A) - moving [3] will look like:

$$\delta x_\Gamma = 0 \quad (2)$$

It is known [4; 5], that along with parities (1) parities also take place:

$$x = \xi \quad (3)$$

where ξ - parameter of clearing from servo-constraint. Zero value of ξ corresponds to communication (1) or its differentiated form.

Differential equations of vibrations of system with absorber have following an appearance:

$$\begin{cases} m\xi + b_\Gamma(\dot{\xi} - \dot{x}_\Gamma) + C_1\xi + C_\Gamma(\xi - x_\Gamma) = Q_0 \sin pt \\ m_\Gamma\ddot{x}_\Gamma + b_\Gamma(\dot{x}_\Gamma - \dot{\xi}) + C_\Gamma(x_\Gamma - \xi) + \frac{dm_\Gamma}{dt}(\dot{x}_\Gamma - \dot{\xi}) = R \end{cases} \quad (4)$$

where R - servo constraints force.

We will set the task: to define, under what law to regulate force of reaction of servo-constraint R , that the servo-constraint (1) it was carried out stability.

Writing down the equations (4) in a kind:

$$(m_\Gamma\ddot{\xi} + b_\Gamma\dot{\xi} + C_\Gamma\xi) - (b_\Gamma\dot{x}_\Gamma + C_\Gamma x_\Gamma) = Q_0 \sin pt$$

$$(m_\Gamma\ddot{x}_\Gamma + b_\Gamma\dot{x}_\Gamma + C_\Gamma x_\Gamma) - (b_\Gamma\dot{\xi} + C_\Gamma\xi) + \frac{dm_\Gamma}{dt}\dot{x}_\Gamma = R \quad (5)$$

and from the second equation of system (5) we will define expression $(b_\Gamma\dot{x}_\Gamma + C_\Gamma x_\Gamma)$, i.e.,

$$(b_\Gamma\dot{x}_\Gamma + C_\Gamma x_\Gamma) = -m_\Gamma\ddot{x}_\Gamma + [b_\Gamma\dot{x}_\Gamma + C_\Gamma x_\Gamma] - \frac{dm_\Gamma}{dt}\dot{x}_\Gamma + R \quad (6)$$

Substituting (6) in the first equation of system (5), we will receive:

$$\begin{aligned} & (m_\Gamma\ddot{\xi} + b_\Gamma\dot{\xi} + (C_1 + C_\Gamma)\xi) - (b_\Gamma\dot{x}_\Gamma + C_\Gamma x_\Gamma) \\ & + m_\Gamma\ddot{x}_\Gamma + \frac{dm_\Gamma}{dt}\dot{x}_\Gamma - Q_0 \sin pt = R \end{aligned} \quad (7)$$

If reaction of servo constraint (1) to form under the law [4, 5, 7]:

$$R = m_\Gamma\ddot{x}_\Gamma - Q \sin pt + \frac{dm_\Gamma}{dt}\xi - k_1\dot{\xi} - k_2\xi \quad (8)$$

where k_1, k_2 - some constants, that, substituting (8) in (7), we will receive the equations of the indignant motion of object:

$$m_\Gamma\ddot{\xi} + k_1\dot{\xi} + (C_1 + k_2)\xi = 0 \quad (9)$$

Equation (9) is the differential equation with constant factors.

4. Investigation of Stability

We investigate on stability not indignant motion:

$$\xi = 0$$

corresponding servo constraint (1). For this purpose we will form the characteristic equation (9), which looks like:

$$m_{\Gamma} \lambda^2 + k_1 \lambda + (C_1 + k_2) = 0 \quad (10)$$

Equation (10) is a quadratic with constant factors. Therefore stability of realization of servo constraint (1) (negativity of the real parts of roots of the characteristic equation) can be investigated by Hurvits's criterion [6]. For this purpose we will make a characteristic determinant (Hurvitsian):

$$\Delta = \begin{vmatrix} m_{\Gamma} & C_1 + k_2 & 0 \\ 0 & k_1 & 0 \\ 0 & m_{\Gamma} & C_1 + k_2 \end{vmatrix}$$

According to Hurvits's theorem, the necessary and sufficient condition of negativity of the real parts of roots of the characteristic equation (a condition of asymptotic stability) for the equation of the second degree will look like [6]:

$$m_{\Gamma} > 0, \quad k_1 > 0, \quad \Delta_1 = m_{\Gamma} > 0$$

$$\Delta_2 = \begin{vmatrix} m_{\Gamma} & C_1 + k_2 \\ 0 & k_1 \end{vmatrix} = m_{\Gamma} \cdot k_1 > 0$$

$$\Delta_3 = \begin{vmatrix} m_{\Gamma} & C_1 + k_2 & 0 \\ 0 & k_1 & 0 \\ 0 & m_{\Gamma} & C_1 + k_2 \end{vmatrix} = m_{\Gamma} \cdot k_1 \cdot (C_1 + k_2) > 0.$$

Hurvits's conditions are led to inequalities:

$$m_{\Gamma} > 0, \quad k_1 > 0, \quad C_1 + k_2 > 0 \quad (11)$$

The conditions (11) express the conditions for the stability of the system and show that, the stability is ensured to ensure the stability of the system in relation to servo-coupling (1), under what conditions the constant coefficients, and the law of variation of the mass of the absorber. It should be noted that, under the conditions (11), there is some arbitrariness, which consists in choosing a way to implement these conditions. So, for example, if we assume that the absorber mass is constant, then from (11) we obtain conditions

$$k_1 > 0, \quad k_2 > 0,$$

which are provided by a suitable choice of fluid viscosity and spring stiffness.

5. Investigation of Realization of Servo-constraint

We will consider the problem of realization of servo constraint (1). As expression (8), force of reaction of servo constraint R shows depends on external disturbing force

$Q \sin pt$, from weight change of $\frac{dm_{\Gamma}}{dt} \dot{x}_{\Gamma}$ absorber (from jet force), from relative speed of absorber $m_{\Gamma} \ddot{x}_{\Gamma}$ and from coordinate and speed of change of a body (1). From works V. V. Rumjantsev [3] and also A. G. Azizov [4; 5] it is known, that an example of the systems, containing servo constraints, are watching systems. Therefore, for the decision of the put question we are offered to use electromechanical watching system (EWS) [6].

The equation of motion of object (of cargo) with holonomic fixed constraints (1) will look like:

$$\begin{cases} (m_{\Gamma} \ddot{\xi} + b_{\Gamma} \dot{\xi} + C_{\Gamma} \xi) - (b_{\Gamma} \dot{x}_{\Gamma} + C_{\Gamma} x_{\Gamma}) = Q_0 \sin pt \\ (m_{\Gamma} \ddot{x}_{\Gamma} + b_{\Gamma} \dot{x}_{\Gamma} + C_{\Gamma} x_{\Gamma}) - (b_{\Gamma} \dot{\xi} + C_{\Gamma} \xi) + J_{\pi} \cdot i_1^2 \cdot \frac{\ddot{x}_{\Gamma}}{r_1} = K_{m_1} \cdot i_1 \cdot I_1 \end{cases} \quad (12)$$

where r_1 - radius of a gear wheel, reformative a rotary motion in the forward; J_{π} - the moment of inertia of an anchor of the electric car (EC) a direct current of independent excitation; i_1 - transfer factor.

As the processes occurring in watching system are interconnected, to the equations of motion of object (of cargo) (12) should be the equations of other elements of watching system are attached. We will form these missing equations.

Usually gauges of measurement (GM) will transform kinematic parameters to pressure [6, 10, 11]. Gauges of measurement (GM) in which quality potentiometers are used, achogenerators, rotating transformers, sensors, etc., can be described by equations [6, 10, 11]:

$$T_1^D \cdot \dot{U}_1^D + U_1^D = K_1^D \xi, \quad T_2^D \cdot \dot{U}_2^D + U_2^D = K_2^D \dot{\xi},$$

$$T_3^D \cdot \dot{U}_3^D + U_3^D = K_3^D \ddot{x}_{\Gamma}, \quad (13)$$

where U^D - target parameter; K^D - transfer factor; T^D - delay time.

Under the scheme of transformation of the joint venture, the received pressure will be transformed to codes [7]:

$$T_{j_1}^{CII} \dot{x}_{j_1}^{CII} + x_{j_1}^{CII} = K_{j_1}^{CII} U_{j_1}^D, \quad (j_1 = 1, 2, 3) \quad (14)$$

where $K_{j_1}^{CII}$ - factor of transfer of the joint venture; $x_{j_1}^{CII}$ - target codes of the joint venture; $T_{j_1}^{CII}$ - delay time, also move on input COMPUTER.

The received codes on COMPUTER are processed and on an exit command codes [7] move:

$$T_1^{IIBM} \dot{x}_1^{IIBM} + x_1^{IIBM} = f_1(x_{\Gamma}, \ddot{x}_{\Gamma}, \xi, \dot{\xi}, \ddot{\xi}, \dots) \quad (15)$$

where x_1^{IIBM} - target parameters (codes) of COMPUTER; T_1^{IIBM} - time of delay of COMPUTER; f_1 - some function of the arguments.

The received command codes in transformer codes to pressure (TCP) will transformed to pressure [7]:

$$T_1^{IKH} \dot{U}_1^{IKH} + U_1^{IKH} = K_1^{IKH} \cdot x_1^{IBM} \quad (16)$$

where U_1^{IKH} - target parameter TCP; T_1^{YII}, K_1^{YII} - time of delay and strengthening factor.

The code converter in pressure (TCP) operates the amplifier-converter (AC), forming managing directors of pressure under the law [7]:

$$T_1^{YII} \dot{U}_1^{YII} + U_1^{YII} = K_1^{YII} \cdot U_1^{IKH} \quad (17)$$

where: U_1^{YII} - pressure on an amplifier-converter (AC) exit; T_1^{YII}, K_1^{YII} - time of delay and strengthening factor.

To the received system of the equations (12) - (17) adding the equations of balance of pressure of a chain of an anchor:

$$L_1 \frac{dI_1}{dt} + R_1 I_1 + K_{w1} \cdot i_1 \cdot \frac{\dot{x}_\Gamma}{r_1} = U_1^{YII} \quad (18)$$

where L_1, R_1 - inductance and active resistance of an anchor chain; I_1, U_1 - a current and pressure of a chain of an anchor;

K_{w1} - factor anti - EMF, we will receive the closed system of the equations (12) - (18).

If in system (12) - (18) instead of the equation (12) to take the equation:

$$m_\Gamma \ddot{x}_\Gamma - Q \sin pt + \frac{dm_\Gamma}{dt} \xi - k_1 \dot{\xi} - k_2 \xi - J_\pi \cdot i_1 \cdot \frac{\ddot{x}_\Gamma}{r_1} - K_m \cdot i_1^2 \cdot I_1 = 0 \quad (19)$$

then, from system of the equations (13)- (19), the law of formation of operating influences (codes) from outside COMPUTER can be defined.

Along with the generalized model of watching system, we will consider the simplified model. For this we assume that:

$$T_1^{IBM} = T_1^{IKH} = T_1^{YII} = L_1 = 0,$$

$$T_j^D = 0, \quad T_{j_2}^{CI} = 0, \quad (j=1, 2, 3; j_1=1, 2, 3) \quad (20)$$

Then, from system of the equations (13)- (19), under conditions (20) we will receive:

$$f_1 + \frac{R_1}{i_1 \cdot K_1^{YII} \cdot K_1^{IKH} \cdot K_m} m_\Gamma \ddot{x}_\Gamma - Q \sin pt + \frac{dm_\Gamma}{dt} \xi - k_1 \dot{\xi} - k_2 \xi + \frac{K_\omega \cdot i_1 \cdot \frac{\dot{x}_\Gamma}{r_1}}{K_1^{YII} \cdot K_1^{IKH}} \quad (21)$$

If on COMPUTER, a part of watching system, we will form operating influences (codes) by the law (21), at assumptions (20), we will receive the equations (10), for which stability conditions of not indignant motion looks like (11).

6. Conclusion

If to consider the generalized model, i.e. not to consider a parity (20), the law of formation of operating influences f_1 can be certain by the numerical decision of system of the equations (13)- (19) by method of Zeydel [9]. For this purpose passing to final parities [9]:

$$\begin{aligned} (\dot{I})_1 &= \frac{(I)_1^{N+1} - (I)_1^N}{h}, \quad \dot{U}_1^{YII} = \frac{(U_1^{YII})^{N+1} - (U_1^{YII})^N}{h}, \\ \dot{U}_1^{IKH} &= \frac{(U_1^{IKH})^{N+1} - (U_1^{IKH})^N}{h}, \\ \dot{x}_1^{IBM} &= \frac{(x_1^{IBM})^{N+1} - (x_1^{IBM})^N}{h} \end{aligned}$$

system (13)- (19) we will lead to a kind:

$$\begin{aligned} (I_1)^{N+1} &= \frac{1}{K_m \cdot i_1} \{ m_\Gamma \ddot{x}_\Gamma - Q \sin pt + \frac{dm_\Gamma}{dt} \xi - k_1 \dot{\xi} - k_2 \xi + \\ &\quad J_\pi \cdot i_1^2 \cdot \frac{\ddot{x}_\Gamma}{r_1} \} \end{aligned}$$

$$(U_1^{YII})^{N+1} = L_1 \left[\left(\frac{(I_1)^{N+1} - (I_1)^N}{h} \right) + i_1 \cdot K_{w1} \cdot \frac{\dot{x}_\Gamma}{r_1} + R_1 \cdot (I_1)^N \right],$$

$$(U_1^{IKH})^{N+1} = \frac{1}{K_1^{YII}} \left[T_1^{YII} \cdot \frac{(\dot{U}_1^{YII})^{N+1} - (U_1^{YII})^N}{h} + (U_1^{YII})^N \right],$$

$$(x_1^{IBM})^{N+1} = \frac{1}{K_1^{IKH}} \left[T_1^{IKH} \cdot \frac{(U_1^{IKH})^{N+1} - (U_1^{IKH})^N}{h} + (U_1^{IKH})^N \right],$$

$$(f_1)^{N+1} = T_1^{IBM} \cdot \frac{(x_1^{IBM})^{N+1} - (x_1^{IBM})^N}{h} + (x_j^{IBM})^N, \quad (22)$$

The system (22) is solved numerically. Following values [10] thus were accepted:

$$K^{IKH}=26, T^{IKH}=0,003 \text{ сек}, i_\pi=50,$$

$$T^{YII}=0,01 \text{ сек}, T^{IBM}=0,001 \text{ сек}, K^{YII}=26$$

We choose the engine 2ПБВ 100L [11]:

$$I_{\text{ном}} = 25 \text{ A } K_\Gamma = 10,8 \text{ мс}$$

$$J_\pi = 13 \cdot 10^3 \text{ кг} \cdot \text{м}^2 K_w = 5,75 \text{ мс}$$

$$L = 0,8 \text{ мГн}$$

It is besides accepted:

$$\tau = 1 \text{ кг}, \quad \dot{\chi} = 3 \text{ сек}^{-1}, \quad \ddot{\chi} = 4 \text{ сек}^{-2}$$

$$J_1 = 2 \text{ кг} \cdot \text{м}^2, \quad \dot{\eta} = 2 \text{ сек}^{-1}, \quad \ddot{\eta} = 2 \text{ сек}^{-2}$$

$$r_1 = 1 \text{ м}, \quad h_{10} = 10, \quad h_{11} = 10$$

$$b = 1 \text{ м}, \quad F = 10 \text{ Н}$$

$$k = 1 \text{ м}, \quad a = 1,5 \text{ м}$$

The received numerical results differ from the theoretical results, calculated at assumptions (20), on 10-15 %.

The work was supported by the Fund for Fundamental Research F-4-14 of the Republic of Uzbekistan.
