Abstract: Influence of high-density drilling fluid weighted with conventional barite, micronized barite, hematite and manganese tetroxide on the wear behavior of N80 metal surface was investigated. The worn surface morphologies and roughness of the N80 metal was observed and tested respectively by scanning electron microscope and surface roughness meter tester. The wear mechanisms of different weighting materials were also discussed. It was found that the erosion rate of N80 steel worn by micronized barite is 57.8% of it worn by conventional barite, and the erosion rate of N80 steel worn by manganese tetroxide is 43.8% of it worn by hematite. The main wear mechanism of conventional barite, micronized barite, hematite and manganese tetroxide on the metal surface is abrasive wear, plowing, planing action and surface fatigue wear, under conditions of high density drilling fluid. Manganese tetroxide and micronized barite can significantly reduce the wear on the metal surface because of filling and adsorption on the concave and convex of the metal surface, especially the roughness of N80 steel surface worn by manganese tetroxide can be reduced to 50% of the hematite.

Keywords: Weighting Materials, Micronized Barite, Manganese Tetroxide, Wear, High-Density Drilling Fluid

1. Introduction

Casing wear is related to drilling fluid, dogleg severity, contact force between drill pipe and casing, and casing steel grade. Weighting material is one of the main factors influencing the casing wear. At the same time, with the development of deep and ultra-deep drilling technology, high-density drilling fluid are widely applied increasingly, the abrasion problems of traditional high-density drilling fluid weighting materials (API barite and hematite) on drill string and casing are becoming more and more prominent [1-4]. Scholars at home and abroad have carried out some researches on function of drilling fluid during the abrasion process. Recently Liang used different steel grade casings to be tested in drilling fluids with different densities. It was found that with the increasing of drilling fluid density, the casing wear rate decreased quickly and then increasing gradually [5]. On the basis of the casing wear prediction model, the effects of dogleg angle, casing steel grade and drilling fluid performance

on the casing wear could be quantitatively analyzed by Yang. The results show that the casing wear depth increases with the increase of dogleg angle, but decreases with the increase of drilling fluid density [6]. But the studies on casing wear are mainly for API barite and hematite.

Micronized barite and manganese tetroxide has become more and more popular weighting material for high density drilling fluid. However, the study of micronized barite and manganese tetroxide on drilling tools and casings are less [7-8]. This paper reviews the influence of high-density drilling fluid with conventional barite, micronized barite, hematite and manganese tetroxide on the wear behavior of N80 metal surface. The wear mechanism of four weighting materials on metal surface will be discussed.

2. Experiment Part

2.1. Instruments and Materials

Instruments: ML-10 abrasive wear testing machine, RM-20

pocket surface roughness meter, electronic balance, Hitachi S-4800 cold field emission scanning electron microscope.

Materials: 1) Drilling fluid additive: Drilling fluid bentonite was provided by Weifang Huawei Bentonite Group Co., Ltd, China, following the API standard. NaOH was purchased from Sinopharm Chemical Reagent Co., Ltd, China. PAC-lv,

SMP-1, SMC, FT-A and Lube was provided by Huaxin Mud Additives Co., Ltd, China.

2) Weighting materials: micronized barite, conventional barite, manganese tetroxide, hematite. The basic parameters of four weighting materials are listed in Table 1.

Table 1. Basic parameters of weighting materials.

weighting materials	Chemical component	density/(g/cm ³)	Moh's hardness	Particle size distribution/ μm			Special surface area/(m ² /g)
				D ₁₀	D ₅₀	D ₉₀	
conventional barite	BaSO ₄	4.21	3.2	1.585	18.24	52.62	0.488
micronized barite	BaSO ₄	4.30	3.1	0.777	2.491	8.302	2.963
hematite	Fe ₂ O ₃	5.15	6.3	6.851	43.12	146.7	0.187
manganese tetroxide	Mn ₃ O ₄	4.82	5.6	0.765	1.149	2.721	4.761

The scanning electron microscope observations of four weighting materials are shown in Figure 1.

Figure 1. SEM photographs of four weighting materials: (a) conventional barite (2000 times), (b) micronized barite (2000 times), (c) hematite (2000 times), (d) manganese tetroxide (5000 times).

2.2. Experiment Design

1) The formula of polymer sulfonated drilling fluid from ultra-deep drilling: 4% bentonite + 0.3%NaOH + 0.3%PAC-lv + 4%SMP-1 + 3.5%SMC + 2.5% FT-A + 2% Lube, drilling fluids' densities are increased to 2.0 g/cm³ by using micronized barite, conventional barite, manganese tetroxide and hematite respectively. After hot rolling at 150°C for 16h, these testing fluids were stirred fully and used for next the next experiment.

2) ML-10 abrasive wear testing machine is used to test the influence of the above testing fluids on casing surface abrasion. Followed by spindle, the disc-shaped samples rotate

and friction emerges by scratching indenter. Its working principle is shown in Figure 2.

Disc-shaped sample and scratching indenter were made of N80 casing material and S135 drill pipe material respectively. Based on the drilling conditions, the rotation speed of turntable was set at 60r/min, the contact pressure between disc-shaped sample and scratching indenter is 25 N, and the speed of indenter moving along turntable is 4 mm/s. During the experiment, four groups of high-density drilling test fluid weighted by conventional barite, micronized barite, hematite and manganese tetroxide are poured into turntable. After running 8 hrs, four N80 steel disc-shaped samples are washed and dried.

Figure 2. Working principle of ML-10 abrasive wear testing machine.

3. Results and Discussion

3.1. The Influence of Weighting Materials on Wear Value

The wear values of four N80 steel disc-shaped samples are shown in Figure 3. As Figure 3 shows, the order of abrasion degree of high-density drilling fluid by adding different weighting materials to N80 steel from high to low is conventional barite, hematite, micronized barite and manganese tetroxide. The wear values of N80 steel by micronized barite is 57.8% of conventional barite; yet the wear values of N80 steel by manganese tetroxide is 43.8% of hematite. It is obvious the abrasion degree of manganese tetroxide and micronized barite to N80 steel are significantly lower than traditional high-density weighting materials.

Figure 3. Influence of different weighting materials on N80 steel abrasion consumptions.

3.2. Influence of Weighting Materials on Metal Surface Abrasion

After worn in test fluids weighted by different weighting materials, the surface scanning electron microscope results of N80 steel disc-shaped sample are shown in Figure 4. Figure 4(a) shows that there are large number of long and continuous abrasive indentation, wide furrows and pits and grooves in different sizes on the surface of N80 steel sample, after worn in conventional barite-based drilling fluid. This is due to the grooves and cracks being plowed on the surface of conventional barite during friction. Metal materials are flaking away, mainly characterized by abrasive wear [9-10].

Figure 4(b) shows that the grooves and pits on the surface of

N80 steel samples are less than conventional barite, after worn in micronized barite-based drilling fluid. Figure 1(a) and Figure 1(b) shows that conventional barite particles are long shapes, while the majority of micronized barite particles are blocky shapes. The size of micronized barite particle is significantly smaller than conventional barite particle, and thus it has higher particle sphericity, the plowing effect on the metal surface is significantly smaller than conventional barite in the process of friction.

Figure 4(c) shows that there are large number of long, deep and continuous pits and grooves on the surface of N80 steel sample, after worn in hematite-containing drilling fluid. And bottom of the grooves is smooth, and appears plastic fracture and flake. This is due to the high hardness of hematite particles (Moh's hardness is 6.3), which have large particle size, irregular polyhedron and sharp edges (as show in Figure 1(c)). Thus the grooves are planed on the surface of wear sample by hematite particles directly during friction [11-12].

Figure 4(d) shows that, compared with the high-density drilling fluid containing conventional weighting materials barite and hematite, wear degree of N80 steel samples in high-density drilling fluid by adding manganese tetroxide is less. The surface of the samples has plastic deformation and horseshoe-shaped shallow pit, followed with shallow scratches, indentations. In Figure 1 (d), manganese tetroxide is spherical particles, and the surface of sample is squeezed repeatedly by manganese tetroxide particles during friction. Fatigue cracks form and particles detach, which result in shallow pits and indentation. Thus it gives rise to surface fatigue wear.

Figure 4. SEM photographs of sample surface after wear in different experiment pulp by adding different weighting materials: (a) conventional barite (1800 times), (b) micronized barite (3500 times), (c) hematite (5000 times), (d) manganese tetroxide (3500 times).

3.3. Influence of Weighting Materials on the Roughness of Metal Surface

RM-20 pocket surface roughness meter is used to test the surface roughness of disc-shaped samples in experiment pulp by adding different weighting materials before and after the wear, the results are shown in Figure 5. After wear in test

fluids weighted by different weighting materials, the roughness of sample surface increase at certain levels. Ra and Rz of N80 steel disc-shaped samples are around 50% of hematite-containing test fluid after wear in manganese tetroxide-containing test fluid, the influence of micronized barite on the roughness of sample surface is less than conventional barite.

Figure 5. Surface roughness of N80 steel in experiment pulp by adding different weighting materials.

Results analysis: Figure 5 shows that before abrasion, Ra on the surface of N80 steel disc-shaped sample is 0.7 μm , Rz is 2.7 μm , and the average particle size of manganese tetroxide and micronized barite is 1.149 μm and 2.491 μm , respectively. The particle sizes are no different with the roughness of sample surface, which make the particles tend to fill in the concave and convex of N80 steel disc-shaped sample surface; while the special surface area of manganese tetroxide and micronized barite particles is 4.761 m^2/g and 2.963 m^2/g respectively. The large special surface area makes the particles easily adsorbed on the concave and convex surface of N80 steel disc-shaped sample [13]. The fill and absorption function of manganese tetroxide and micronized barite on metal concave and convex surface are shown in Figure 6. The fill and adsorption function on metal surfaces and higher degree of particles sphericity could reduce the cutting action on the metal surface during friction, and thus the roughness of sample in the experiment pulp by adding manganese tetroxide and micronized barite is lower after wearing. The particle size of conventional barite and hematite are larger and the shapes are irregular, so the roughness of samples in conventional barite and hematite is larger after wearing.

Figure 6. Reaction of manganese tetroxide and micronized barite on the metal concave and convex surface: (a) Manganese tetroxide, (b) Micronized barite.

4. Conclusion

The abrasion of conventional barite and micronized barite are mainly particle abrasion. Compared with conventional

barite, the particle size of micronized barite is smaller and the sphericity is higher, which could reduce abrasion. The wear mechanism of metal surface by hematite is planning and manganese tetroxide is fatigue. The spherical particles could significantly reduce the abrasion of metal surface.

The abrasion of manganese tetroxide and micronized barite can be reduced on metal surface due to their small particle size, large special surface area and easy fill and absorption on N80 steel concave and convex surface.
