Abstract: Pattern Division Multiple Access (PDMA) is a novel non-orthogonal multiple access scheme proposed to meet up the diverse demands on high capacity and large number of connections in the fifth generation (5G) wireless networks. PDMA uses the characteristic pattern to define the sparse mapping from data to a group of resources, and the sparsity of the pattern gives impacts on the capacity performance and detection complexity. The present thesis emphasizes greatly to develop a simulation model for the 5G compatible downlink Pattern Division Multiple Access (PDMA) scheme implemented wireless communication system. The simulated system incorporates a modern channel coding ((3, 2) SPC) and different low order digital modulation (4-QAM, QPSK and DQPSK) schemes. With implementation of $G^{[2,3]}_{PDMA}$ pattern matrix for three users and considering total transmitted power of 40 Watt, 50%, 30% and 20% of total transmitted power have been assigned to first, second and third users and additionally phase shifting factors have been applied in power scaled transmitted signals of second and third users to resolve ambiguity in individual data separation. On consideration of both synthetically generated binary data stream and color image transmission in AWGN and Rayleigh fading channel, it is observable from MATLAB based simulation study that the ((3, 2) SPC) channel encoded simulated system is very much robust and effective in retrieving transmitted data. The impact of applicability of 2-D median image filtering technique in processing of three different identically sized color images and enhancement of image quality has clearly been observed. This thesis elucidates the benefits of multi-user data transmission in power domain.

Keywords: PDMA, ((3, 2) SPC), $G^{[2,3]}_{PDMA}$ Pattern Matrix, AWGN and Rayleigh Fading Channel, 2-D Median Image Filtering Technique

1. Introduction

Multiple access scheme is generally regarded as the landmark of each generation of mobile communication systems. In the first generation (1G), Frequency division multiple access (FDMA) was used. Time division multiple access (TDMA) and code division multiple access (CDMA) were introduced in the second generation (2G) and the third generation (3G) respectively. Orthogonal frequency division multiple access (OFDMA) is considered as the key component of the fourth generation (4G). The multiple access schemes separate users in orthogonal resources such as frequency, time, or code domain resources. These orthogonal

multiple access (OMA) schemes make it possible to build the system with low complexity, however they are unable to achieve the capacity boundary of a multi-user channel. The fifth generation (5G) needs to support much higher capacity and also provide much larger number of connected users. These requirements are rather challenging and it is difficult to satisfy the requirements by using OMA schemes. Non-orthogonal multiple access (NOMA) has thus been considered as a promising candidate to meet the requirements in connection numbers and system capacity of 5G. Signal of multiple users are superposed and advanced detection algorithm are employed to separate the superposed signal. Theoretically, NOMA is optimal in terms of achieving the

capacity boundary [1,2]. In the previous 3G WCDMA wireless communication system, NOMA has been used. In the uplink of WCDMA, data symbols are spread by long spreading codes and multiple users transmit their spread signals on the same frequency and time resources. Since long spreading codes are used, only linear detection algorithm is possible at the receiver due to the complexity of non-linear detection algorithm. As a result, non-orthogonal transmission of this type is demonstrated to be inefficient in terms of spectrum efficiency [3]. A number of NOMA techniques are studied in both industry and academy, such as interleaved division multiple access (IDMA) [4], bit division multiplexing (BDM) [5], sparse code multiple access (SCMA) [6] and multi-user sharing access (MUSA) [7] etc. With IDMA, different users are distinguished by user-specific interleavers. BDM was first proposed to provide differentiated services for broadcasting system. It extends the multiplexing from symbol level to bit level. Both SCMA and MUSA are based on code domain superposition [8]. In 2016, Chen and et.al., suggested various nonlinear detection algorithms such as successive interference cancellation (SIC), maximum a posteriori (MAP) or maximum likelihood (ML) in receiving section for separating users being multiplexed on the same resource. Pattern Division Multiple Access (PDMA) is a code pattern based NOMA scheme. The PDMA patterns are designed to offer different order of transmission diversity, so that disparate diversity order between multiple users could be introduced to alleviate the error propagation problem of SIC receiver. In transmission diversity, multiple copies of a signal are transmitted from independent resources to avoid transmission error due to deep fading on one resource. The resources could be time, frequency or spatial resource. The PDMA pattern is also extended to include power scaling and phase shifting to harvest additional constellation shaping gain. In PDMA, non-orthogonal transmission is realized through multiplexing data of multiple users onto the same resource group with different PDMA pattern.

2. PDMA Pattern Design and Signal Detection

Users multiplexed PDMA pattern on the same resource group can construct a PDMA pattern matrix. Each column of the PDMA pattern matrix represents a PDMA pattern. Properties of PDMA pattern matrix such as dimension and level of sparsity contribute both complexity and system performance. In our present study, a 2×3 PDMA pattern matrix has been used where 3 users are multiplexed on two resource elements (REs). The PDMA pattern in such case can be written as:

$$G_{PDMA}^{[2,3]} = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \end{bmatrix} \quad (1)$$

Taking PDMA pattern $G_{PDMA}^{[2,3]}$, transmitted data of 3

users are mapped onto two REs. The transmission signal on these REs can be expressed as:

$$\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} \quad (2)$$

where, v_j is the transmission signal on the j^{th} RE, and x_k is the modulation symbol of the k^{th} user

Unlike orthogonal transmission, transmission signal on each RE is linear combination of multiple modulation symbols:

$$V_1 = x_1 + x_2 \quad (3)$$

$$V_2 = x_1 + x_3$$

To resolve ambiguity in proper detection of user's own data, power scaling and phase shifting are introduced in PDMA pattern matrix. Specifically, before two users' symbols are mixed, a power scaling factor and a phase shifting factor are applied:

$$v = \sqrt{\beta} x_1 e^{j\phi} + \sqrt{1-\beta} x_2 \quad (4)$$

where, β is the power scaling factor and ϕ is the phase shifting factor. In this present study, merely phase shifting factor has been applied to data of user #2 and user #3. As each user is equipped with a single antenna and base station is equipped with two antennas, the fading channel matrix is 2×3 sized and it is represented as:

$$H_{CH} = \begin{bmatrix} h_{11} & h_{12} & h_{13} \\ h_{21} & h_{22} & h_{23} \end{bmatrix} \quad (5)$$

The PDMA equivalent channel response matrix H can be written as:

$$H = H_{CH} \Theta G_{PDMA}^{[2,3]}$$

$$= \begin{bmatrix} h_{11} & h_{12} & h_{13} \\ h_{21} & h_{22} & h_{23} \end{bmatrix} \begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \end{bmatrix} = \begin{bmatrix} h_{11} & h_{12} & 0 \\ h_{21} & 0 & h_{23} \end{bmatrix} \quad (6)$$

where, Θ has been considered to represent element-wise product of two matrices. In PDMA equivalent channel response matrix H , the channel coefficients of first, second and third columns are applicable to user #1, user #2 and user #3 [9]. As signal transmitted from Base station from two antennas use different resource (frequency), the signal received at user #1 from second antenna of Base station is neglected. The signal received at the user #1, user #2 and user #3 can be written as:

$$y_1 = h_{11}(x_1 + x_2) \quad (7)$$

$$y_2 = h_{12}(x_1 + x_2) \quad (8)$$

$$y_3 = h_{23}(x_1 + x_3) \quad (9)$$

From equation (7) through equation (9), it is observable that in every cases, another user's data are treating as interference which are needed to be eliminated. Primarily, digitally modulated complex symbol vectors for three users $\hat{x}_1, \hat{x}_2$ and $\hat{x}_3$ are scaled in power such that the average power for each user is made to unity. If P be the total transmitted power and β_1, β_2 and β_3 are the power scaling factors (0.5, 0.3 and 0.2) of three users, ϕ_2 and ϕ_3 are phase scaling factors for user #2 and user #3, the power and phase scaled signal vector of the three users can be written as:

$$\begin{aligned}\hat{x}_1 &= \sqrt{P\beta_1} \hat{x}_1 \\ \hat{x}_2 &= \sqrt{P\beta_2} \hat{x}_2 e^{j\phi_2} \\ \hat{x}_3 &= \sqrt{P\beta_3} \hat{x}_3 e^{j\phi_3}\end{aligned}\quad (10)$$

On applying OFDM modulation to each data vector presented in Equation (10), the transmitted signal vectors for three users x_1, x_2 and x_3 are produced. In receiving section of each user, the AWGN noise contaminated Rayleigh faded signal is undergone OFDM demodulation. The OFDM demodulated signal vectors x_{10}, x_{20} and x_{30} are channel equalized and can be written as:

$$\begin{aligned}x_{11} &= (h_{11})^{-1} x_{10} \\ &= \sqrt{P\beta_1} \hat{x}_1 + \sqrt{P\beta_2} \hat{x}_2 e^{j\phi_2}\end{aligned}\quad (11)$$

$$\begin{aligned}x_{22} &= (h_{12})^{-1} x_{20} \\ &= \sqrt{P\beta_1} \hat{x}_1 + \sqrt{P\beta_2} \hat{x}_2 e^{j\phi_2}\end{aligned}\quad (12)$$

$$\begin{aligned}x_{33} &= (h_{23})^{-1} x_{30} \\ &= \sqrt{P\beta_1} \hat{x}_1 + \sqrt{P\beta_3} \hat{x}_3 e^{j\phi_3}\end{aligned}\quad (13)$$

In equation (11) through (13), $\hat{x}_1, \hat{x}_2$ and $\hat{x}_3$ are the detected power scaled complex modulated symbol vectors for three users. These signal vectors are assumed to have average power of unity which are further rescaled to retrieve original signal vectors. In equations (11), (12) and (13), $\sqrt{P\beta_2} \hat{x}_2 e^{j\phi_2}, \sqrt{P\beta_1} \hat{x}_1$ and $\sqrt{P\beta_1} \hat{x}_1$ are the interference terms, denoting $X = \{x^{(1)}, x^{(2)}, x^{(3)} \text{ and } x^{(4)}\}$ is the power scaled (unity average power) signal alphabet of 4QAM/QPSK/DQPSK and using ML decoding, the detected interfering complex symbols $\bar{x}_1, \bar{x}_2$ and $\bar{x}_3$ contained in interference term for user #1, user #2 and user #3 can be obtained from:

$$\bar{x}_1 = \arg \min_{x^{(k)} \in X} |x_{11} - \sqrt{P\beta_1} \hat{x}_1 - \sqrt{P\beta_2} x^{(k)} e^{j\phi_2}|, k = 1, 2, 3, 4 \quad (14)$$

$$\bar{x}_2 = \arg \min_{x^{(k)} \in X} |x_{22} - \sqrt{P\beta_1} x^{(k)} - \sqrt{P\beta_2} \hat{x}_2 e^{j\phi_2}|, k = 1, 2, 3, 4 \quad (15)$$

$$\bar{x}_3 = \arg \min_{x^{(k)} \in X} |x_{33} - \sqrt{P\beta_1} x^{(k)} - \sqrt{P\beta_3} \hat{x}_3 e^{j\phi_3}|, k = 1, 2, 3, 4 \quad (16)$$

The detected power scaled complex symbols $\hat{x}_1, \hat{x}_2$ and $\hat{x}_3$ for three users can be written as:

$$\hat{x}_1 = (x_{11} - \sqrt{P\beta_2} \bar{x}_1 e^{j\phi_2}) / (\sqrt{P\beta_1}) \quad (17)$$

$$\hat{x}_2 = (x_{22} - \sqrt{P\beta_1} \bar{x}_2) / (\sqrt{P\beta_2} e^{j\phi_2}) \quad (18)$$

$$\hat{x}_3 = (x_{33} - \sqrt{P\beta_1} \bar{x}_3) / (\sqrt{P\beta_3} e^{j\phi_3}) \quad (19)$$

On multiplying Equation (17) through Equation (19) with normalization factor $NF (= \sqrt{2})$, the original complex digitally modulated data symbols for user #1, user #2 and user #3 are achieved viz.

$$\hat{\hat{x}}_1 = NF \hat{x}_1 \quad (20)$$

$$\hat{\hat{x}}_2 = NF \hat{x}_2 \quad (21)$$

$$\hat{\hat{x}}_3 = NF \hat{x}_3 \quad (22)$$

3. Channel Coding and Image Filtering Techniques

3.1. (3, 2) SPC Channel Coding

In SPC (Single parity check) channel coding, the transmitted binary bits are rearranged into very small code words consisting of merely two consecutive bits. In such (3, 2) SPC coding, a single parity bit is added to the message $u = [u_0, u_1]$ so that the elements of the resulting code word $x = [x_0, x_1, x_2]$ where, $x_0 = u_0$, $x_1 = u_1$ and $x_2 = u_0 \oplus u_1$, the symbol $\oplus$ is indicative of the sum over GF (2) [10]

3.2. 2D Median Filtering

2D median filtering is widely used to remove various types of 'pepper' and 'Gaussian' type noises. In this paper 2D Median Filtering scheme is utilized in which a 3×3 neighborhood windowing mask is used for simply sorting all the pixel values within the window and finding the median value and replacing the original pixel value with the median value [11].

4. System Description

The block diagram of the 5G compatible downlink Pattern

Division Multiple Access (PDMA) scheme implemented wireless communication system model has been presented in Figure 1. In such simulated model, RGB color image will be processed. The RGB color image is different for three users but each is of identical size (260 pixels (width) and 140 pixels (height)). The chosen color image is primarily converted into its respective three Red, Green and Blue components. Its each components is undergone integer to binary converted (not shown in the Figure), channel coded with various Forward Error Correction codes (FEC). The processed binary data are digitally modulated using low order digital modulations, power scaled and phase inserted (in case of signals for user 2 and user 3), serial to parallel converted, OFDM modulated, parallel to serial converted, power rescaled and phase removed, digitally demodulated, channel decoded and eventually transmitted color image / binary data are retrieved. Our presently considered simulated system is working in MATLAB environment based on the simulation parameters presented in Table.

of Base station. The signal transmitted from two transmitting antennas are in different resource elements such that the frequency of transmitted carrier is different. In receiving section of each user, own transmitted signal is detected along with other user's signal transmitted in identical resource element considered as interference. The received signal is processed for interference reduction and subsequently sent up to the serial to parallel (S/P) converter, OFDM demodulated, parallel to serially converted, power rescaled and phase removed, digitally demodulated, channel decoded and eventually transmitted color image / binary data are retrieved. Our presently considered simulated system is working in MATLAB environment based on the simulation parameters presented in Table.

Figure 1. Block diagram of 5G Compatible Downlink Pattern Division Multiple Access (PDMA) scheme implemented Wireless Communication System.

Table 1. Summary of the simulated model parameters.

Parameters	Values
Size of Color image for each user	140 pixels× 260 pixels
PDMA pattern matrix	$G_{PDMA}^{[2,3]}$
Total transmitted power (Watt)	40
Assigned power to user 1, user 2 and user 3 (of total transmitted power)	50%,30% and 20%
Phase introduced intranmitted signals of user 2 and user 3	π and $\pi/4$
Channel encoding	(3,2) SPC
Symbol mapping	DQPSK, QPSK and QAM
Image filter	2-D median
Signal to noise ratio, SNR (dB)	0-15

It is keenly observable from graphical illustrations presented in Figure 2 through Figure 4 that the performance

of the downlink (3,2) SPC channel encoded PDMA scheme based 5G compatible simulated wireless communication system is very much well defined. In all cases, the simulated system shows comparatively better performance in QAM as compared to QPSK and DQPSK digital modulations. On critical observation of simulation curves shown in Figure 2, it is seen that for a typically assumed SNR value of 5 dB, the estimated BER values are 0.1859, 0.2462 and 0.3763 which are indicative of system performance improvements of 1.2201 dB and 1.8425 dB in case of QAM as compared to QPSK and DQPSK digital modulations. At 20% BER value, SNR improvements of 6 dB and 12 dB are achieved in case of QAM as compared to QPSK and DQPSK digital modulations.

Figure 2. BER performance of (3,2) SPC channel encoded downlink Pattern Division Multiple Access (PDMA) scheme implemented 5G compatible wireless communication system for user #1 under utilization of various digital modulation schemes.

The BER performance presented in Figure 3 is applicable for user #2. For a typically assumed SNR value of 5 dB, the estimated BER values are 0.2996, 0.3326 and 0.4513 which ratify system performance improvements of 0.4538 dB and 1.3254 dB in case of QAM as compared to QPSK and

DQPSK digital modulation techniques. At 25% BER value, SNR improvements of 1 dB and 7 dB are achieved in case of QAM as compared to QPSK and DQPSK digital modulation techniques.

Figure 3. BER performance of (3,2) SPC channel encoded downlink Pattern Division Multiple Access (PDMA) scheme implemented 5G compatible wireless communication system for user #2 under utilization of various digital modulation schemes.

On graphical illustration presented in Figure.4, it is observable that the overall system performance is not suitable for user #3 as power assigned is low as compared to user #1 and user #2. For a typically assumed SNR value of 5 dB, the estimated BER values are 0.3204, 0.3337 and 0.4546 which are indicative of system performance improvement of

0.1766dB and 1.3427dB in case of QAM as compared to QPSK and DQPSK digital modulation techniques. At 25% BER value, SNR improvements of 1dB and 4dB are achieved in case of QPSK in comparison to QAM and DQPSK digital modulation schemes.

Figure 4. BER performance of (3,2) SPC channel encoded downlink Pattern Division Multiple Access (PDMA) scheme implemented 5G compatible wireless communication system for user #3 under utilization of various digital modulation schemes.

Figure 5. Transmitted color images for three users (Top for user #1, middle for user #2 and bottom for user #3).

Figure 5 shows the three identical sized color images which are considered to have been assigned to the three users. In purpose of showing pixel distributions in the color images,

they are converted into gray forms (Figure 6) and corresponding histograms are presented in Figure 7. It is keenly observable that the pixel distributions in the images are not identical to each other. In assigned image for user #1, the pixel distribution with pixel values in the approximate range: 120-130 are very much prominent in comparison to others.

Figure 6. RGB to Gray converted images for three different users.

Figure 7. Histograms of RGB to Gray converted images for three different users (Top for user #1, middle for user #2 and bottom for user #3).

Figure 8 shows received color images for user #1 at SNR values of 0 dB, 5 dB, 10 dB and 15 dB under scenario of with and without implementation of 2D image noise reduction technique and utilization of QAM digital modulation in (3,2) SPC channel encoded simulated system. In studying with non using 2D image noise reduction technique, the estimated BER values are found to have values of 0.2566, 0.1926, 0.1442 and 0.0790 in case of 0 dB, 5 dB, 10 dB and 15 dB SNR values. Figure 8 also ratifies that the quality of the retrieved images is improved with application of 2D image noise reduction technique. Figure 9 shows received color images for user #2 at SNR values of 0 dB, 5 dB, 10 dB and 15 dB under scenario of with and without implementation of 2D image noise reduction technique and utilization of QAM digital modulation in (3,2) SPC channel encoded simulated system. In studying with non using 2D image noise reduction technique, the estimated BER values are found to have values of 0.0.3704, 0.3030, 0.1701 and 0.0798 in case of 0 dB, 5 dB, 10 dB and 15 dB SNR values. Figure 9 also ratifies that the quality of the retrieved images is improved with application

of 2D image noise reduction technique although the 30% of total power has been assigned to user #2. Figure 10 shows received color images for user #3 at SNR values of 0 dB, 5 dB, 10 dB and 15 dB under scenario of with and without implementation of 2D image noise reduction technique and utilization of QAM digital modulation in (3,2) SPC channel encoded simulated system. In studying with non using 2D image noise reduction technique, the estimated BER values are 0.3726, 0.3203, 0.2261 and 0.1513 for SNR values of 0 dB, 5 dB, 10 dB and 15 dB. Figure 10 also confirms that the quality of the retrieved images is improved with application of 2D image noise reduction technique although the 20% of total power (smallest power) has been assigned to user #3. Figure 11 through Figure 13 show graphical illustrations for RGB to Gray converted transmitted and retrieved color images with and without filtering at 10 dB SNR value for different users in (3,2) SPC channel encoded simulated system. It is observable that in each cases presented filtered image has resemblance with the original image.

Figure 8. Sequential received color images for user #1 at SNR values of 0 dB, 5 dB, 10 dB and 15 dB under scenario of with and without implantation of 2D image noise reduction technique (color images presented in Left column and Right column imply the case of without and with implementation of 2D image noise reduction technique).

Figure 9. Sequential received color images for user #2 at SNR values of 0 dB, 5 dB, 10 dB and 15 dB under scenario of with and without implantation of 2D image noise reduction technique (color images presented in Left column and Right column imply the case of without and with implementation of 2D image noise reduction technique).

Figure 10. Sequential received color images for user #3 at SNR values of 0 dB, 5 dB, 10 dB and 15 dB under scenario of with and without implantation of 2D image noise reduction technique (color images presented in Left column and Right column imply the case of without and with implementation of 2D image noise reduction technique).

Figure 11. 3-Dimensional Graphical illustrations showing RGB to Gray converted transmitted and retrieved color images with and without filtering at 10 dB SNR value for user #1 in (3,2) SPC channel encoded simulated system (Top for original, middle for without filtering and bottom for filtering).

Figure 12. 3-Dimensional Graphical illustrations showing RGB to Gray converted transmitted and retrieved color images with and without filtering at 10 dB SNR value for user #2 in (3,2) SPC channel encoded simulated system (Top for original, middle for without filtering and bottom for filtering).

Figure 13. 3-Dimensional Graphical illustrations showing RGB to Gray converted transmitted and retrieved color images with and without filtering at 10 dB SNR value for user #3 in (3,2) SPC channel encoded simulated system (Top for original, middle for without filtering and bottom for filtering).

5. Conclusions

In this paper, an comprehensive study has been undertaken on the performance evaluation of 5G Compatible Downlink Pattern Division Multiple Access (PDMA) scheme implemented Wireless Communication System. In such work, an effort has been taken to show the suitability of PDMA scheme in multi-user's data retrieval. To discriminate individual user's signal, phase scaling factors have been introduced and implementation of 2D spatial domain noise reduction technique is found to have produced reasonably watchable color images. Numerical results ratifies the significance of utilizing digital modulation, power assignment and channel coding schemes. In the context of system performance, it can be concluded that the implementation of low order QAM digital modulation technique in (3,2) SPC channel coding scheme provides satisfactory result for such a 5G Compatible Downlink Pattern Division Multiple Access (PDMA) scheme implemented Wireless Communication System.
