Abstract: Platelets are derived from megakaryocytes and help in hemostasis and produce growth factors. Platelet count and MPV are parameters used in various conditions and vary with age and sex. The purpose of this study was to compare platelet count and MPV of healthy young with healthy elderly and calculate normal range of platelet count and to find relationship of platelet count and MPV with age and sex. Prospective study was done on 202 people visiting hematology department of BPKIHS, 100 as cases and 102 as controls, after obtaining ethical clearance. Only the consenting individuals and individual meeting inclusion criteria were included in the study. Blood sample was drawn in EDTA vial and Platelet counts and MPV was measured by 5 part hematology analyzer. Results showed that platelet count is higher in females and young individuals while platelet volume is higher in elderly. Study shows that there is insignificant difference between platelet count and MPV between elderly population and young control. Thus, from this prospective study conducted on 202 people we concluded that there is a rise in MPV with age and decrease in platelet count. However, the difference is insignificant and does not mandate separate reference range for various age groups.

Keywords: Platelets, Platelet Count, Mean Platelet Volume

1. Introduction

Ageing is decrease in working capacity of different organ system leading to increased chances of dysfunction and disease. Decline in pluripotent cytokines and growth factors result in decrease in haematopoietic stem cells disrupting normal system [1]. Hence, age factor should be considered [2]

Megakaryocytes fragments in the bone marrow to produce platelets which help in hemostasis and produce growth factors. Decrease or increase in their number and function cause platelet disorders [3].

Platelets lack nucleus and circulate at 150,000 to 450,000/mm³. [4]. Platelets are smaller in size and arise from larger megakaryocytes which are polyploidy. Variations in platelet size are determined at the time of synthesis in bone marrow and these differences may cause cardiac problems [5] MPV tells about the size of platelets [6]. And sufficient

platelet count is necessary for hemostasis. [7] Thus, platelet count and MPV also help in determining thrombotic potential [8].

Platelet heterogeneity arise at thrombopoesis. Aging is not responsible for decrease in platelet size rather they are independent determinants of platelet function [9].

Studies done on fewer individuals by using manual counting techniques were used to calculate normal platelet counts and these values are used by standard hematology textbook. It is easier to conduct platelet count studies on a large group of individuals with precision because of automatic counting and data processor tools. This research aims at determining the mean platelet counts in males and females of different age groups and finding out if there is any significant variation between age groups

Patients commonly undergo complete blood count.. Previous researches have shown platelet counts to be significantly higher in women [4, 10]. There is still much to

know about variations in platelet counts in healthy adults.

2. Rationale

BPKIHS is a tertiary care Centre located in eastern region of Nepal. In this study we will investigate about changes in platelet counts and mean platelet volume with increasing age. We will investigate difference in platelet counts and platelet volume with respect to gender. Since there have been no research conducted in the past in Platelet counts and Mean Platelet Volume in elderly in BPKIHS, we want to calculate the suitable range and relationship with aging.

According to research conducted in Nigeria [11], there was significant gender dependent variations in platelet count and mean platelet volume. Moreover, platelet count was found to decrease with age. So, we have chosen this topic:

1. To compare platelet counts and mean platelet volume of healthy controls of age group 20 – 30 years and healthy cases of age group 50 and above

2. To find suitable reference values of platelet counts and mean platelet volume in elderly males and females

3. Objectives

1. Primary objective:

To compare platelet counts and mean platelet volume of healthy controls of age group 20 – 30 years and healthy cases of age group 50 and above.

2. Secondary objectives:

1) To find out suitable values of platelet counts and mean platelet volume in elderly males and females

2) To find out relationship between platelet size and number

4. Literature Review

Studies on platelet counts have shown that number of platelets decreases with age so that thrombocytopenia was rare in young people whereas thrombocytosis was common. [12].

Blood cell counts in elderly people above 65 years showed blood cell count to be significantly different for males and females except for basophils. Hence, blood cell count should be gender specific. [13]

Females have higher platelet counts compare to males (261 vs. 237 $\times 10^9/L$, $P < 0.001$), and platelet number fell with increasing age, with a decrease from infancy to old age of 35% in males and about 25% females. This falling trend common in all investigated populations. Platelet count in population under 15 years was significantly higher compared to the population above 15 years and below 65 years (299 vs 252 $\times 10^9/L$, $P < 0.001$), and platelet count in population of 15-64 years was significantly higher when compared to population over 64 years (252 vs 233 $\times 10^9/L$, $P < 0.001$). Under 15 years of age, variation in platelet count of men and women was not significant (298 vs 299 $\times 10^9/L$, $P = 0.690$), but women of age range 15–64 years and over 64 years had

significant difference (264 vs 238 $\times 10^9/L$, $P < 0.001$) and (245 vs 220 $\times 10^9/L$, $P < 0.001$) respectively. [12]

The mean platelets count of 218.90 $\times 10^9/L$ and 247.8 $\times 10^9/L$ were determined among men and women blood donors respectively. Statistically insignificant rise in platelet count was noted ($P = 0.01$). Similar insignificant difference was noted in case of MPV ($P = 0.01$). This study showed platelet count to be sex specific and gender should be considered while diagnosing thrombocytopenia [14]

Likewise, increased platelet count in females 252.35 \pm 41.25 $\times 10(9)/l$ as compared to men 221.87 \pm 37.63 $\times 10(9)/l$ ($p = 0.0002$) was noted and statistically insignificant differences were noted in case of MPV by Butkiewicz AM et al. Platelet count is sex variable, being higher in females than males [4].

5. Materials and Methods

Study setting: BPKIHS, Dharan Municipality of Sunsari District.

Study group: Elderly men and women of age group 50 and above years visiting Hematology lab of BPKIHS as cases and healthy males and females of age group 20 -30 years as controls.

Sample size: 202

100 cases: 47 Males and 53 Females

102 controls: 29 Males and 73 Females

Sampling frame: people who visited hematology department of BPKIHS

Inclusion Criteria:

Males and females aged 50 and above years. Similarly, young adults aged 20 - 30 years were used as control.

Exclusion Criteria:

Males and females not giving verbal consent.

No history of terminal illness like carcinoma, thalassemia, sickle cell disease, tropical diseases like malaria, dengue, no history of blood loss or blood transfusion in last six months

Data Collection Tools:

Data collection will be carried out at Hematology Department of BPKIHS. Face to face interview will be taken to fill the semi-structured questionnaire.

Platelet counts and Mean Platelet Volume was measured by 5 part differential hematology analyzer which measured 22 parameters in total. 2 ml of venous blood from each case and control was collected into sodium citrate vials. The analyzer reports within 1 minute and can keep back record up to 1000. This method is faster than manual method.

Ethical clearance:

Ethical clearance was obtained from Institutional Ethical Review Board of BPKIHS.

Statistical analysis:

All interviewed questionnaire was indexed and kept on file. Database was entered in Microsoft Excel 2007 and converted into SPSS 11.5v for statistical analysis. For descriptive statistics mean and Standard deviation will be calculated along with it tabular presentation will be made. For inferential statistics, χ^2 , z or U test will be applied to find

out the significant difference between platelet count in elderly and young at 95% confidence interval where $p = 0.05$.

RESEARCH PROCESS (thorough and clear description of all data gathering processes that will take place)

1. The study requires patients' participation in a face to face interview to discuss questions related to research.
2. They need to show us their OPD card and lab investigation reports.
3. They have the total will to leave the interview, and it's their choice to voluntarily take part in the interview.

6. Results

The mean platelet count was $200.36 \times 10^9/L$ with 94.695 S. D. in healthy elderly males and $207.13 \times 10^9/L$ with 68.965 S. D. in females. There was an insignificant decrease ($P > 0.05$) in the mean platelet count in the healthy aged males and females when compared with $190.67 \times 10^9/L$ with S. D 60.774 $\times 10^9/L$ in males and $227.93 \times 10^9/L$ with S. D.66.371 $\times 10^9/L$ in female healthy young adult control. Mean platelet count in young adult control was higher but the rise was insignificant ($P > 0.05$) (Table 3).

MPV in the elderly men was 10.31fl with S. D. 1.49 and females was 10.72fl with S. D. 1.769fl and in young controls was 10.93fl with S. D 1.80 fl in females and 10.58fl with S. D 1.86 fl respectively. The fall in mean platelet volume in the healthy aged population was statistically insignificant ($P > 0.05$) compared to that of the young adult population (Table 3). Inverse correlation between mean platelet count and mean platelet volume ($r = 0.001$) was noted.

Table 1. Platelet number and size in elderly.

Parameters	Males (n=47)	Females(n=53)
Platelet counts	200.36X 109/L	207.13 109/L
MPV	10.31fl	10.72fl

Table 2. Platelet number and size in controls.

Parameters	Males (n=27)	Females(n=73)
Platelet counts(X 109 / l)	190.67	227.93
MPV in fl	10.58	10.93

Table 3. Platelet count and MPV in Males/Females and cases/controls.

Sex	Platelet Count	MPV	Number
Male	211.43	10.697030	126
Female	198.58	10.451316	76
Parameter	Platelet Count	MPV	Number
Controls	218.76	10.86	102
Cases	203.95	10.53	76

7. Discussion

Results from this study showed that more platelets are found in females and young individuals whereas lesser in elderly and males. Sex specific variation in platelet count was shown amongst the Algerians [15]. [4] observed higher count in females.

Decline in platelet count in healthy elderly males and females noted in this study may be due to hookworm infestation which is common in Nepal. Likewise, increased fatty tissue replacement of bone marrow, impaired cytokine production in the aged population, low intake iron, protein, vitamins and folic acid. Malaria, dengue and malignancy can result in decline in platelet count but only healthy population was taken into account in this study.

Large platelets produced in response to decrease platelet counts were found to be less reactive. [9]. Mean platelet Volume depends on thrombopoietic conditions.

Inverse correlation between platelet count and MPV was observed [11].

But unlike their findings [12], the platelet count in male control is less than those of elderly males and platelet count in the age range 20-30 years was insignificantly higher when compared to subjects over 49 years. Women had more platelets in the age range 15-64 years (264 vs $238 \times 10^9/L$, $P < 0.001$) and over 64 years (245 vs $220 \times 10^9/L$, $P < 0.001$) [12]). We found similar increase but the increase was insignificant.

With the advent of technology and awareness, more and more blood counts are being done, it is crucial to avoid sending unnecessary investigations for age and sex related variation in platelet count. Further studies are to be conducted among a large healthy population for accurate reference values for male and female. On the contrary to the study conducted amongst Nigerians [11], this study suggests that there is an insignificant variation in platelet count and mean platelet volume calculated between the healthy aged population and the young adult control ($P > 0.05$). Therefore separate values for platelet count and mean platelet volume for the elderly is not necessary. Hence, the same reference values $150 \times 10^9/l$ and 6.5 to 12.0fl. Moreover, the increase in platelet count in females was insignificant on the contrary to findings of [13] but agrees with findings of [14]. So, normal ranges for haematological indices need not be sex-specific.

8. Conclusion

Thus, from this prospective study conducted on 202 people we concluded that there is a rise in MPV with age and decrease in platelet count. However, the difference is insignificant and does not mandate separate reference range for various age groups.
