Prevalence and Determinants of Malnutrition Among Schoolchildren in Primary Schools in the Communes of Dixinn, Matam and Matoto, Conakry, Guinea, 2016. *Central African Journal of Public Health*. Vol. 4, No. 2, 2018, pp. 38-47. doi: 10.11648/j.cajph.20180402.12

Received: February 19, 2018; Accepted: March 19, 2018; Published: April 14, 2018

Abstract: Malnutrition leads to disruption of cognitive development and poor academic performance among children. However, few studies have been conducted in primary school to measure its burden and risk factors in Guinea. The objective of this study was to measure the prevalence of malnutrition and determine its associated factors among primary school children in Conakry, Guinea. A cross-sectional study was conducted from December 1st, 2015 to March 31st, 2016 among fifth grade primary school children in three communes of Conakry, Guinea. Children aged between 8 to 19 years were randomly selected using a two-stage sampling technic. Data on socio-demographic characteristics, of both children and their parents, and food habits were collected. The Z-scores of height-for-age and body mass index (BMI) were generated using SPSS macro 2007 developed by WHO for the analysis of anthropometric data for children aged between 5-19 years. Acute malnutrition was defined as a weight-for-height z-score ≤ -2.0 standard deviation (SD) and a chronic malnutrition was considered as a height-for-age z-score ≤ -2.0 standard deviation (SD). A multivariable logistic regression analysis was conducted to assess factors associated with acute or chronic malnutrition among children. A total of 2,408 children were included in the analysis. The mean age was 12.5 ± 1.8 years, and 53.4% were female. The prevalence of acute malnutrition was 11.8% (95% CI: 10.6-13.2) and that of chronic malnutrition was 13.7% (95% CI: 12.1-14.9). Being a male (AOR = 1.88, 95% CI: 1.45-2.45, $p < .001$), living in the communes of Dixinn (AOR = 3.78, 95% CI: 2.53-5.65, $p < .001$) and Matoto (AOR = 3.45, 95% CI: 2.29-5.20, $p < .001$) were associated with chronic malnutrition.

<.001), as well as having a father who was a trader (AOR = 1.66, 95% CI: 1.15-2.41, $p = .007$) were statistically significantly associated with acute malnutrition. Children attending Matoto schools (AOR = 3.72, 95% CI: 2.68-5.16, $p < .001$) were independently associated with chronic malnutrition. Acute and chronic malnutrition were common in primary school children in Conakry. Targeted awareness raising actions must be undertaken with the parents of those who have an important risk.

Keywords: Prevalence, Determinants, Malnutrition, Primary School, Guinea

1. Introduction

In developing countries, malnutrition and undernutrition are common despite the relative economic growth observed [1]. It can disrupt children's cognitive development and lead poor academic performance [2-4]. Malnutrition affects 200 million children worldwide including more than 20 million severe and acute malnutrition in developing countries [5, 6]. In sub-Saharan Africa, various socio-economic factors have been associated with children's nutritional status, such as maternal and paternal education, parental income, and family assets [7]. A literature review on the nutritional status of children worldwide are mainly focus on children under 5 years of age. So, what about school-aged children? School-age children constitute an important part of the global population and more than 75 per cent live in developing countries [8]. This period of transition from childhood to adolescence requires a healthy and balanced diet for better health in adulthood, while physical, emotional and social changes occur among them [9]. In 2016, chronic malnutrition affected approximately 154.8 million children under-five worldwide of which 90% occurred in Africa and Asia [5, 6]. In addition, 20 million children suffer from severe acute malnutrition, most of whom live in South Asia and Sub-Saharan Africa [6]. Data on the nutritional status of school-age children at the national level in developing countries are seldom [10]. Nevertheless, some researchers have investigated the nutritional status of school-age children in sub-Saharan Africa [11]. These different researches have focused on thinness, growth retardation, overweight and obesity as well as lifestyle and food behavior, micronutrients deficiencies [12-18]. In brief, these studies suggest that undernutrition is still prevalent in West Africa and severe malnutrition, micronutrient deficiencies, growth retardation, thinness or underweight are commonly diagnosed among children whose nutritional state had been evaluated [11]. Given its impact on health, and education, malnutrition is a major obstacle to human development and economic growth in poor countries and especially among the most vulnerable [19]. As a result, malnourished children are less likely to perform well in school and more likely to become malnourished adults and at higher risk of illness and premature death [19]. Researchers report that nutritional status might has a positive influence on cognitive development and academic performance [20-23]. In Guinea, data on the prevalence, risk factors and consequences of malnutrition are very rare. Among the few conducted, all of them only focused on children under five. One of these studies was highly disseminated through the 2012

Demographic and Health Survey. This study reported 10% of acute malnutrition, 31% of chronic malnutrition, and 20% underweight children of five years [24]. Additionally, the results of the SMART survey conducted in 2015 showed that 8% of children aged less than 59 months were malnourished acute and 25.9% of children aged 6-59 months chronically malnourished [25]. The determinants of nutritional status of school-aged children remain poorly documented in the study area. Thus, the present study was designed to measure the prevalence and analyze the determinants of malnutrition in fifth grade primary school children aged 8 to 19 years in three communes of Conakry, Guinea.

2. Materials and Methods

2.1. Study Setting, Design and Population

A cross-sectional study was carried out on 2,408 pupils, aged between 8-19 years and attending either public or private schools, in three communes of Conakry, Guinea. The study was conducted from December 1st, 2015 to March 31st, 2016. Conakry, the capital of Guinea is composed of five communes (Kaloum, Dixinn, Matam, Ratoma and Matoto) and has 1,660,973 inhabitants, 50% of them being females [26]. Each commune has its own Educational Direction. The present study was carried out in three Communal Education Directorates (Dixinn, Matam and Matoto)

Children of fifth grade from public or private primary schools in the three selected communes were included. Children of 5th grade were targeted as they likely understand and easily answer a questionnaire as compared to those in the lower grades. Those in the 6th grade were not included due to their unavailability regarding their exam preparations. Moreover, the level of children in the 5th year is very close to that of the 6th grade students. The programs taught are almost the same and the children of both classes are almost the same age.

2.2. Sample

At least, 756 children per commune were required for this Study. In total, 2,268 children were included. These children were randomly selected using a two-stage sampling technic. The first sampling consisted of random selection of primary schools from the list provided by education directorates from the three communes. Second sampling, children of the 5th grade presenting in the selected schools the day of the survey and accepting to be enrolled in this study were included.

2.2.1. Primary Schools' Selection for Participation

Schools with at least 250 children were purposively selected. This choice was guided by concern not to be confronted with a lack of children given the heterogeneity observed in the enrolment of primary schools in Conakry. The list of schools was obtained from the communal education directorates. This list initially included 615 primary schools of which 212 met inclusion criteria. These schools were composed of 132 private and 80 public schools. The commune of Dixinn was composed of 92 schools

divided into 75 private (81.5%) and 17 public (18.5%) schools. Matam had 94 schools including 68 private (72.3%) and 26 public (27.7%). Matoto had 429 primary schools including 386 private (90.0%) and 43 public (10.0%). At Matam 39 schools (nine private and four public schools) were included, 35 schools in Dixinn (16 public and 19 private) and finally in 13 schools in Matoto (12 private schools and one public school) [27]. The number of public and private schools surveyed by commune was based on the weight of each commune (*Figure 1*).

Figure 1. Schoolchildren' inclusion flowchart in the study.

*Schools with all primary classes and a minimum of 250 schoolchildren

** Number of schools to investigate = Minimum size per commune / Average number of children per class in Guinea [27]

Minimum size per commune = 831 and average number of children per class in Guinea = 60 [27]

*** Type of school per commune in total

Number of school type: Number of schools to investigate per commune x Rate of each type of school in the total number of schools by commune

2.2.2. Choice of Children

The study surveyed all 5th grade children from the primary schools selected in each commune.

2.3. Data Collections

The data were collected using a standardized questionnaire including the sociodemographic characteristics of both the children and their parents (age, sex, weight, height, level of education, marital status, type of school attended, and food habits). Data on food habits included the food consumed (fruits, vegetables, meat, fish, liver, sweets and sweetened beverages) by the children during the last 7 days preceding

the survey, as well as the foods regularly eaten by the parents and children' friends.

2.4. Anthropometrics Measures

The height of the children was measured twice while standing on a flat surface without shoes. The tape measure was placed at the heels of the children and at the back of the neck and the measure was read. When the difference between two successive measurements exceeded 0.5 cm, a third measurement was made, and the two closest measurements were considered. Additionally, children were weighted by using an electronic scale of 0.1 kg accuracy. Two

measurements were successively carried out. When the difference between the two measurements exceeded 0.2 kg, a third measurement was made, and the two closest measurements were taken into consideration. After each series, a tare was used for the verification of the scale.

2.5. Screening of Malnutrition Status

All anthropometric measurements were done using WHO guide for anthropometric measurements by trained data collectors. Two anthropometric indices were used including the z-score of the height for age and the z-score of BMI for age were calculated according to the World Health Organization reference 2007 for 5-19 years [28]. Acute malnutrition was defined as a weight-for-height z-score less than -2.0 and a chronic malnutrition was considered as a BMI-for-age z-score less than -2.0 [28, 29]. Malnutrition was moderate when z-score was between -3.0 and -2.0 and severe when it was less than -3.0 [28, 29]. Z-scores for weight and height were generated using SPSS macro developed by WHO for the analysis of anthropometric data for children aged 5-19 years [29].

2.6. Statistical Analysis

Chi-square test or Fisher's exact test was used as the test of trend for compared categorical variables. The independent sample t-test was used for quantitative variables. Multivariate logistic regression model was performed to identify factors associated with malnutrition. All potential risk factors significant at the 0.20 level in univariate analysis were entered the model. The goodness-of-fit of the models was assessed by the Hosmer-Lemeshow test. After double data entry using Epidata 3.1, all statistical analyses were performed using the Statistical Package for Social Sciences (Version 21, Chicago, IL). A probability level of ≤ 0.05 was considered statistically significant.

2.7. Ethical Considerations

Children's assent and parental oral consent were required. The study protocol was approved by the scientific committee of the Department of Public Health, Faculty of Medicine,

Gamal Abdel Nasser University of Conakry.

3. Results

3.1. Socio-Demographic Characteristics of Children and Their Parents

The study included 2,408 children in 5th grade frequenting primary schools in three (3) communes (Dixinn, Matam and Matoto) of Conakry. Of these, 35.3% were from Dixinn, 32.0% from Matam and 32.6% from Matoto. The mean age of children was 12.5 ± 1.8 years. The mean age of the parents was 46.8 ± 10.0 years for fathers and 36.4 ± 7.8 years for mothers. Among the fathers, 41.6% have informal activities, followed by public or private officers 30.9% and traders 14.7%. Many of them have attended school, of which 23% had attended secondary level and 32.9% high level. Among the mothers, 32.5% were traders, 30.9% were housewives. Of these, 23.6% had primary level, 17.3% a secondary level and 11.4% a high level.

3.2. Food Habits of Children

Children were asked about their daily food habits. Results showed that 54.7% took usually at least three meals, 34.8% took two meals, 8.9% took one meal. Their food habit included fish (98.9%), beverages (98.1%), candies (97.3%), fruits (87%), meat (80.7%), and vegetables (69.4%).

3.3. Acute Malnutrition

Tables 1 and 2 show the characteristics of children according to their nutrition status as well as those of their parents and their food habits. The proportion of acute malnutrition in children was 11.8% (95% CI: 10.6-13.2), of which 3.7% (95% CI: 3-4.5) suffered from a severe acute malnutrition and 8.1% (95% CI: 7-9.2) from moderate acute malnutrition. The prevalence of acute malnutrition was different among the communes ($p < 0.001$): Dixinn (16.1%), Matoto (14.0%) and Matam (4.7%). It was higher in boys than girls (15.4% vs. 8.7%, $p < 0.001$).

Table 1. Characteristics of acute malnourished children and non-acute malnourished in three communes (Dixinn, Matam, Matoto) of Conakry, 2016.

Schoolchildren characteristics	Acute malnourished n (%)	Non-Acute malnourished n (%)	p-value
Mean age	12.5 $\pm$ 1.8	12.5 $\pm$ 1.8	.51
Gender			<.001
Boys	172 (15.4)	946 (84.6)	
Girls	111 (8.7)	1169 (91.3)	
Pocket money			.11
No money	6 (2.1)	64 (3.0)	
Sometimes	97 (34.3)	592 (28.0)	
Often	41 (14.5)	290 (13.7)	
Always	139 (49.1)	1169 (55.3)	
Type of school			.07
Public schools	103 (36.4)	887 (41.9)

Matam	36 (4.7)	727 (95.3)	
Matoto	110 (14.0)	674 (86.0)	

3.4. Chronic Malnutrition

Table 3 and 4 show the characteristics of chronic malnourished children and chronic non-malnourished children as well as those of their parents and their eating habits. The prevalence of chronic malnutrition was 13.5% (95% CI: 12.1-14.9), or 3.3% (95% CI: 2.6-4) of severe

chronic malnutrition and 10.2% (95% CI: 8.9-11.4) of moderate chronic malnutrition. The prevalence of chronic malnutrition was significantly different according to the communes ($p < .001$): Matam (23.1%), Dixinn (10.3%) and Matoto (7.6%). The prevalence of chronic malnutrition was higher among boys than girls (17.0% vs. 10.4%, $p < .001$).

3.5. Factors Associated with Acute and Chronic Malnutrition

The results of the multivariate analysis showed that male children were twice likely to be severely malnourished (AOR = 1.88, 95% CI: 1.45-2.45, $p < .001$), 5 compared to girls. Children who attended schools in Dixinn (AOR = 3.78, 95% CI: 2.53-5.65, $p < .001$) and Matoto (AOR = 3.45, 95% CI: 2.29-5.20, $p < .001$) were three times more likely to be severely malnourished (Table 5). Children whose father trade (AOR = 1.66, 95% CI: 1.15-2.41, $p = .007$) were twice likely to be acutely malnourished. For chronic malnutrition, children attending Matoto commune (AOR = 3.72, 95% CI: 2.68-5.16, $p < .001$) were four times more likely to be chronically malnourished.

4. Discussion

This study measured the prevalence and analysed factors associated with acute and chronic malnutrition among children of fifth grade in primary schools in three communes of Conakry, Guinea. The overall prevalence of acute malnutrition was 11.8% including 3.7% of children suffering from severe acute malnutrition and 13.5% of chronic malnutrition, including 3.3% of children suffering from severe chronic malnutrition. According to the 2012 Demographic and Health Survey, 31% of children under five in Guinea suffer from chronic malnutrition and 10% from acute malnutrition [24]. The prevalence observed in this study amply demonstrates the extent of the phenomenon of acute and chronic malnutrition in primary schools in the city of Conakry. The frequency of thinness is a serious (10-14%) threshold according to WHO indicators [30]. Moreover, this study showed the unexpected prevalence in an urban area, particularly the capital city, where living standard is supposed to be the highest in the country [24]. The low income of the household, the household and children food habits and their lifestyles could explain these figures of malnutrition observed in current study. Several studies reporting malnutrition on its various forms have been conducted among children in sub-Saharan Africa and elsewhere. A study conducted in Thad, reported 18.7% of chronic malnutrition among children aged between 6- 15 years [31]. A study conducted among children in urban and peri-urban areas of Ouagadougou reported a prevalence of

chronic malnutrition at 8.8% and that of acute malnutrition at 1.7% [17]. A prevalence of acute malnutrition of 17.4% in primary and secondary schools in south western Nigeria had also been reported [32]. Another study among children aged between 5- 17 years old in the city of Dakar recorded 4.9% of chronic malnutrition and 18.4% of acute malnutrition [33]. A study conducted in southern Ethiopia showed 10.3% of chronic malnutrition and 14% of acute malnutrition [34]. Other researchers reported high prevalence of 33.3% for chronic malnutrition and 31.0% for acute malnutrition among 12- to 18-year-olds attending 3 secondary schools in Nsukka, in the urban state of Enugu in Nigeria [35]. In Iran, a study in the northern region of the country revealed 4.93% of chronically malnourished schoolchildren and 5.13% of acute malnourished children [36]. Other researchers found 12.5% and 9.0% respectively of acute malnourished and chronically malnourished schoolchildren in Semnan (a province in the central region of Iran) [37]. These differences in prevalence compared to this study results may be explained by differential dietary intake, socio-economic and cultural differences rather than differences in their genetic potential [14].

The prevalence of chronic malnutrition, which is the most serious and whose consequences are almost irreversible, was different among the included communes. The highest proportions of chronic malnutrition were found in Matam (23.1%) and Dixinn (10.3%) communes than Matoto (7.6%). In Guinea, socio-economic level of the household in which the child is living influences the prevalence of chronic malnutrition. The EDS data constructs the Household Economic Well-Being Index using data on dwelling characteristics and household holdings through a principal component analysis. The results showed that 41% of households are at level 2 on a scale of 1 (the poorest) to 5 (the richest). In current study, the prevalence of chronic malnutrition was different according to the residence of the children. This difference could be explained by socio-economic determinants. Matam and Dixinn communes are coastal zones inhabiting artisanal harbours and the large market of Guinea. In the artisanal harbours of these communes, women practice daily small-scale trade and fish drying at the Madina market. The time devoted to these socio-economic activities means that they give practically no time to primary health care and prevention of malnutrition. We also hypothesize that access to health care facilities for the prevention and management of malnutrition could also

explain this difference. Indeed, Matam commune, which has the highest proportion of chronic malnutrition, has only one public health centre for primary health care and malnutrition management.

This study showed that boys were more acutely malnourished than girls. Moreover, the results of multivariate analysis pointed out that male gender was an independent risk factor for acute malnutrition occurrence. Other studies carried out in Africa [38, 39] and elsewhere [40, 41] have reported similar results. Furthermore, chronic malnutrition seemed equally more frequent in boys. Similar trends were observed in EDS 2012, where the prevalence of chronic malnutrition was slightly higher among males than females (33% versus 30%) [24]. However, in studies conducted in India [42] and Makurdi in Nigeria [43] girls were more chronically malnourished than boys. These results can be explained by the fact that in Africa girls are closer to their mothers. They often attend the kitchen where they have easier access to food than boys. While boys are not often engaged in cooking activities like girls therefore they are more exposed

This study has some limitations. The cross-sectional design should be considered as a limitation when interpreting the findings. Data on the food habits of the children would be useful if collected prospectively. Health-related data such as malaria, intestinal helminthiasis, anemia, vitamin A deficiency, highlighted as being correlated with undernutrition by some authors [44-46] and which have a negative impact on nutritional status [47, 48] and the cognitive development and academic performance of school children [49-51] were not evaluated in this study. Also, micronutrient intake in children was not assessed. However, to this knowledge, this study is one of the few of its kind using a large sample to assess malnutrition in primary schools in Conakry. It included over 2,000 children randomly selected. The study raises the issue of nutritional education and awareness raising based on the development of programs and strategies involving parents and schools to address malnutrition in primary schools in Conakry. In addition, the present study points the need for a nationwide study to better explore the issue. The results can also be used to set up an epidemiological surveillance system on the nutritional status of school children.

5. Conclusion

Despite public efforts in Conakry, the findings of this study shows that acute and chronic malnutrition were common in primary school of Conakry. The differences were found in the different communes and between boys and girls. Given the increasing prevalence of acute and chronic malnutrition in the schoolchildren, the current study suggests that preventive strategies and educational programs be implemented in Conakry primary school. Additionally, the study recommends that awareness-raising actions be undertaken with parents of those at high risk of malnutrition.
