Abstract: Snake venoms are rich in phospholipase A2 (PLA2) and their hydrolysis of cell membrane phospholipids explains the role of the enzyme in venom toxicity. Calcium is known to play an important role at the active site of PLA2 during catalysis. In this study, molecular dynamics simulations of free PLA2 and calcium bound PLA2 were carried out using GROMACS 4.5.5 to evaluate the role of calcium in PLA2 catalysis. The results showed that calcium induced formation of helical structures between Arg62 - Lys66, Asn107 - Tyr111 and Asp114 - Cys119 in PLA2 which with time disappeared through the formation and opening of loops. Calcium induced atomistic movements and conformational changes in snake venom PLA2 which led to the formation of a widened cleft at the active site of calcium bound PLA2 when compared with free PLA2. This could lead to a better binding and accommodation of substrate, thus enhancing catalysis. This study confirms the role of calcium towards the action of PLA2 in snake venom toxicity and could provide useful information for the design of small molecules that can function as PLA2 inhibitors.

Keywords: Snake Venoms, Phospholipase A2, Calcium, Catalytic Site, Inhibitors of PLA2, Loop

1. Introduction

Phospholipases A2 (PLA2) (EC.3.1.1.4) catalyze the hydrolysis of the 2-acyl ester linkage of 1, 2-diacyl-3-sn-phosphoglycerides, with calcium (Ca^{2+}) requirement [1, 2] producing fatty acids and lysophospholipids [3]. Snake venoms are particularly rich in PLA2s [4] and PLA2s are able to induce several biological effects, such as pre-synaptic or post-synaptic neurotoxicity, cardiotoxicity, myotoxicity, platelet aggregation, oedema, haemolysis, anticoagulation, convulsion, and hypotension [5]. Their catalytic activity upon cell membranes of tissues suggests an important role of the enzyme in venom toxicity [6]. It has been reported elsewhere [3] that Asp49 is required for catalysis on artificial substrates. Also, studies have shown that snake venoms PLA2 need submicromolar concentrations of Ca to be catalytically active and also increase in Ca is needed for both binding and catalysis [7, 8]. A researcher [9] has described the calcium binding loop in myotoxicity of PLA2 and concluded that

calcium binds to His48 of PLA2 located at the catalytic site of the enzyme activating it towards its toxic function. Also, His48 is involved in catalysis through orientation of its N-1 group to solvent [10]. Group II PLA2s display a binding site for Ca^{2+} , which is highly conserved (X28CGXGG33) in addition to the highly conserved catalytic site (D42XCCXXHD49) previously reported [11]. The Ca^{2+} binding site is formed by the β -carboxyl group of Asp49 and the carbonyl groups of Tyr28, Gly30 and Gly32 [12]. The active site of snake venom PLA2 has been studied but the role of calcium on the dynamical properties of the catalytic site of the enzyme is limited. This study investigated the role of calcium on dynamical properties of snake venom phospholipase A2 by molecular dynamics simulations.

2. Methodology

2.1. Molecular Dynamics Simulation

GROMACS 4.5.5 was employed to carry out molecular

dynamics simulations of free phospholipase A2 and its complex with calcium using Gromos53a6 force-field parameters [13]. The crystal structure coordinates of PLA2 obtained from RCSB Protein Databank (PDB ID: 3NJU) was considered for the simulation of free PLA2 and calcium bound PLA2 after editing with UCSF chimera 1.9 [14]. Both free and calcium bound structures of PLA2 was inserted into a simulation box with minimum 15 Å distance between the box edge [15]. The boundaries were treated with periodic boundary condition involving the immersion of the simulation unit in periodic images of itself in the x, y and z directions. The setup was subjected to 225 steps of *in vacuo* energy minimization using steepest descent algorithm. Then the systems were solvated using pre-equilibrated coordinates of the SPC explicit water model [16]. Sodium and chloride ions (Na^+ and Cl^-) were added to neutralize the system and to model physiological salt concentration of 154 mM. The system was further minimized using 300 steps of steepest descent algorithm followed by 50 ps of position restrained dynamics where proteins were kept fixed by adding restraining forces, but water molecules were allowed to move. The P-LINCS [17] algorithm was used to constrain bond lengths, allowing the use of 2 fs time steps. Short-range non-bounded interactions were truncated at 12 Å and employed the particle-mesh Ewald method [18, 19] in computing the long-range electrostatic interactions. Final production simulations were performed in the isothermal isobaric (NPT) ensemble at 300 K, using v-rescale [20] as external bath with a coupling constant of 0.1 ps. Pressure was kept constant (1 bar) by using the time-constant for pressure coupling of 0.5 ps and Parrinello-rahman barostat [20] for pressure coupling. Both free phospholipase A2 and its complex with calcium were subjected to 5000 ps (5.0 ns) molecular dynamics simulations and conformations generated during the simulations were stored every 2 ps.

2.2. Data Analysis

All the analyses were carried out using the available trajectory analysis tools of GROMACS packages. Visualization of molecular coordinates and rendering was achieved with VMD version 1.9.1 [21] and graphs were plotted with xmgrace on Linux platform.

3. Results and Discussion

To explore the role of calcium on the structure and function of PLA2, dynamic structural properties such as root mean square deviation (RMSD) and radius of gyration (Rg) of both calcium free and calcium bound PLA2 were obtained from molecular dynamics (MD) simulations analysis and presented in Figure 1.

The RMSD of atoms of the simulated protein over time is a reliable parameter to analyze the stability of the system. As evident from Figure 1, the first 0.2 ns of both simulations were considered to be the equilibration phase where slight structural re-organization takes place and properties were averaged over the last 5.0 ns of the simulations. RMSD and

Rg are two important parameters that provide quantitative descriptions of changes in the tertiary structure of the simulated protein. Similar RMSD were observed for free and calcium bound PLA2, which were 0.2332 ± 0.0212 nm and 0.2389 ± 0.0208 nm respectively. The calculated Rg value for free PLA2 was 1.4526 ± 0.0139 nm, while that of calcium bound PLA2 was 1.4469 ± 0.0125 nm. Essentially unchanged values of RMSD and Rg of free and ligand bound PLA2 signify no significant structural change of the venom protein PLA2 in the presence of calcium. Although there were no significant structural changes of PLA2 in the presence and absence of calcium when averaged over the last 5 ns of the simulations but deviations at 0.562, 1.258 and 4.916 ns (Figure 1) were of interest to mention. Therefore, snapshots of atomistic details as well as key interactions occurring in free and calcium bound PLA2 at 0.562, 1.258 and 4.916 ns were obtained and presented in Figure 2. Between 0.4 – 1.0 ns of the simulation, calcium bound PLA2 was more stable than free PLA2 whereas between 1.1 – 1.5 ns and 4.8 – 5.0 ns free PLA2 was more stable than calcium bound PLA2 (Figure 1A). Figure 1B showed that Rg of calcium bound PLA2 between 0.4 – 1.0 ns was lower than that of free PLA2 whereas between 1.1 – 1.5 and 4.8 – 5.0 ns free PLA2 showed lower radius of gyration.

Figure 1. Variation of (A) RMSD and (B) Radius of gyration with simulation time for free PLA2 (black) and calcium bound PLA2 (red) obtained from molecular dynamics simulation.

At 0.562 ns, calcium bound PLA2 MD retained a helical structure (Helix 1) between Asp114 to Cys119 when compared with PLA2 structure at 0.0 ns which was not observed in the free PLA2 MD (Figure 2A). Also at 0.562 ns, calcium bound PLA2 MD showed an additional helical structure (Helix 2) between Arg62 to Lys66 (Figure 2A). It is important to note that at 0.562 ns MD, the loops (Loop 1 and 2) of calcium free PLA2 deviated more than those of calcium bound PLA2 when compared with the loops of PLA2 at 0.0 ns (Figure 2). At 1.258 and 4.916 ns, the helical structure (Helix 1) in calcium bound PLA2 disappeared and there was the appearance of a third helical structure (Helix 3) between Asn107 to Tyr111 which was not retained at 4.916 ns in calcium free PLA2 (Figure 2 B and C). Again at 1.258 and 4.916 ns, the loops (Loop 1 and 2) of calcium bound PLA2 deviated more than that of calcium free PLA2 when compared with the loops of PLA2 at 0.0 ns (Figure 2 B and C). These results indicate that calcium initially induces formation of helical structures (between Arg62 to Lys66 and Asn107 to Tyr111) in snake venom PLA2 which starts to disappear with the formation and opening of loops (Figure 2). The observed relatively opened loop in calcium bound PLA2 indicate that calcium plays a crucial role in PLA2 loop flexibility and function. To have an idea of the regions of free and calcium bound PLA2 that are more flexible, the RMSF of free and calcium bound PLA2 were calculated and presented in Figure 3.

Figure 2. Snapshots of PLA2 obtained from molecular dynamics simulation at (A) 0.562 ns, (B) 1.258 ns and (C) 4.916 ns. Blue represent PLA2 at 0.0 ns, red is free PLA2 while purple is calcium bound PLA2. Loops and helical structures are coloured yellow. Calcium is represented as light green sphere.

From the RMSF results (Figure 3), calcium free PLA2 from snake venom showed more flexibility between amino acid residues of Val13 – Ser15, Asp21 – Phe22, and Cys79 – Lys80 while that of calcium bound PLA2 showed more flexibility between residue ids of Cys29 – Gly30 and Asn57 – Ser59 (Figure 3). This suggests that one of the roles of calcium in PLA2 is to increase flexibility of some essential amino acid residues. Another important aspect observed from the MD simulation was the distance between calcium and some amino acid residues at the catalytic site and most

flexible regions of PLA2. The minimum distance between calcium and amino acids at the peaks of the flexible regions including some amino acids (His48, Asp49) at the catalytic site were calculated and the results presented in Figure 4.

Figure 3. Variation of RMSF with simulation time for free PLA2 (black) and calcium bound PLA2 (red) obtained from molecular dynamics simulation.

Figure 4. Minimum distance between calcium and some amino acids (Pro14, Phe22, Gly30, His48, Asp49, Ser59 and Lys80) during molecular dynamics simulation.

The minimum distances between calcium and some residues (Pro14, Phe22, Gly30, His48, Asp49, Ser59 and Lys80) were calculated during MD simulation and the results are shown in Figure 4. The results (Figure 4) showed that Asp49 maintained average distance of 0.2601 ± 0.0092 nm from calcium during the first 2.186 ns of the simulation and 0.4906 ± 0.0903 nm from 2.186 to 5.0 ns of the simulation. During the first 0.930 ns of the simulation, Gly30 maintained an average minimum distance of 0.2501 ± 0.016 nm from calcium which increased to 0.6344 ± 0.1322 nm for the last 5.0 ns. It is also important to note that His48 had an average distance of 0.5787 ± 0.1001 nm from calcium during the first 3.286 ns of the simulation which increased to $0.8918 \pm$

0.1095 nm for the last 5.0 ns. During the dynamics, the increase in the distance between calcium and the amino acids at the catalytic site and most flexible regions of PLA2 suggests that calcium stimulates the movement of amino acids at the catalytic site and most flexible regions of PLA2 to create a widened cleft to accommodate the substrate/ligand. Figure 5 depicts the extent of calcium on the widening of the active site of PLA2. This could explain the observations made elsewhere [7, 8] that snake venom PLA2

need submicromolar concentrations of Ca to be catalytically active and that increase in Ca is needed for both binding and catalysis. Also, it was observed elsewhere [22] that snake venom PLA2 activity was enhanced by Calcium and inhibited by Magnesium, Cobalt and Copper. They suggested that this could be as a result of probable modification of enzyme protein conformation after binding differently from the pattern calcium does, and hence causing a decrease in the enzyme action.

Figure 5. Snapshots of active site of PLA2 obtained from molecular dynamics simulation at (A) 0.562 ns, (B) 1.258 ns and (C) 4.916 ns. Orange is free PLA2 while gray is calcium bound PLA2. Calcium is represented as blue sphere while the region of the active site is represented as red circle.

Wider cleft were observed in calcium bound PLA2 than free PLA2 at 1.2582 and 4.916 (Figure 5 B and C). The widening of the cleft was not observed at 0.562 ns of the simulation probably due to the initial formation of a helical structure (Helix 1) in calcium bound PLA2 but not in free PLA2 (Figure 2). The widening of the cleft could likely lead to better accommodation/binding of substrate, hence efficient catalysis.

4. Conclusion

Considering the results of this study, calcium induces atomistic movements and conformational changes in snake venom PLA2 which leads to formation of wider cleft at the active site of calcium bound PLA2 when compared with free PLA2. The results of this work have shed more light into the mechanism of action of calcium in snake venom toxicity and could be helpful to design small molecules which could function as novel inhibitors of PLA2 as none is available as drug in the market [23]. Such molecules would likely act by inhibiting the formation of loops or its flexibility and/or stabilization of the generated helical structures which would prevent the widening of the cleft at the active site of PLA2. Any molecule with such a mechanism of action would be a potent inhibitor of PLA2.
