Received: May 8, 2020; **Accepted:** May 26, 2020; **Published:** June 3, 2020

Abstract: Background and objective: We found that the phenomenon of unreasonable use of gargles is common in clinical practice, which is closely related to the lack of recognition of gargles by dentists. In this study, some dentists in Hebei province of China were investigated to find some problems with their cognition and some reasonable suggestions were put forward. Methods: 600 dentists were chosen by stratified random sampling. A self-designed questionnaire was distributed online to study the knowledge of those dentists with different professional titles on the gargles types, drug resistance, adverse reactions, potential risks and anti-Candida albicans. 576 questionnaires were collected, of which 528 were valid. All valid questionnaires were analyzed by SPSS21.0 software. Results: As for the gargle types, doctors who knew nothing about it accounted for 15.15%. 51.52% of the dentists did not pay attention to the drug resistance. As for the adverse reactions of compound chlorhexidine gargle, doctors who chose "no adverse reactions" and "unclear" accounted for 8.71% and 32.58% respectively. The awareness of "taste change" of primary dentists was lower than that of senior dentists ($P < 0.05$). As for the potential risks of long-term and frequent use of gargles, 87.50% of doctors chose "Oral flora disorder". Doctors who chose other risks were relatively few accounting for 6.44%, and those who chose "unclear" accounted for 12.12%. As for the cognition of gargles against Candida albicans, 7.58% of dentists chose "unclear". Conclusion: The overall cognition of gargles by dentists with different titles is not comprehensive or accurate.

Keywords: Dentists, Gargles, Cognition, Survey

1. Introduction

Gargles are commonly used therapeutic drug for adjuvant treatment of such oral diseases as periodontal disease, caries, and oral mucosal disease. They have good effects in eliminating oral odor, reducing oral bacteria, preventing dental caries, anti-inflammatory and analgesic [1-4], which has increasingly been recognized by dentists and patients. However, as prescription drugs, they have strict indications and contraindications, and their side effects cannot be ignored. The full cognition of gargles by a professional dentist is directly related to the patients' medication effect and safety.

In this study, a questionnaire survey was conducted among dentists in a province of China to preliminarily grasp the

cognitive situation of dentists about gargles, and to analyze and discuss the results of the survey. By presenting relevant data, dentists were encouraged to further study the theoretical knowledge and spur the research development of gargles, thereby promoting the scientification of clinical use of them.

2. Materials and Methods

2.1. Sample and Setting

A cross-sectional survey was conducted in Hebei Province, China, from November 6-9, 2018. Stratified random sampling was used to select 600 study participants who were dentists in stomatology department of general hospitals, dental specialty

hospitals, community hospitals, dental clinics in Hebei Province of China. We stratified the sample by titles: senior title, intermediate title, primary title and ungraded. To be eligible their working experience needs to be over one year. Stomatology educators responsible for stomatological management/teaching were excluded.

2.2. Design and Contents of the Questionnaire

The questionnaire includes 11 questions, with 6 single-choice questions and 5 multiple-choice questions and consists of two parts: 1. basic information of the dentists, including the name, level and major, as well as the title and age of the respondents. 2. gargles-related knowledge of dentists, including types, drug resistance, adverse reactions, potential risks, and the killing of *Candida albicans*. Face validity was obtained by three professional dentists reviewing a draft questionnaire. The questionnaire was made available online as a web-based link and tried out with the participants. No formal pilot study of the questionnaire was performed. The responding reported no significant issues, so the questionnaire was considered acceptable and a link to the final version was emailed to the target participants. Incomplete questionnaires were excluded to preserve the accuracy of the analysis.

2.3. Data Collection

An online questionnaire survey was distributed to dentists. The online survey was performed via e-mails that contained a link to an online questionnaire, which were sent to the e-mail addresses of the targeted hospitals or clinics. The survey respondents were anonymous and not linked to the submitting source, so that response rates were not known by the original disseminated e-mail addresses. The questionnaire was accompanied by detailed instructions. If there was any doubt in the filling process, the respondents could get any help and explanations by the investigators. In order to minimize communicating between the subjects, the questionnaire system was only open for 72 hours.

2.4. Statistical Method

Statistical Program for Social Sciences 21.0 software (SPSS21.0, Inc., Chicago, IL, USA) was used to analysis the data. χ^2 test or Fisher exact probability method was used to compare the cognition of gargles among dentists with different professional titles. The test level was $\alpha=0.05$, $P<0.05$. The difference was statistically significant.

2.5. Ethical Clearance

This study had been approved by the ethics committee of Stomatology Hospital of Hebei Medical University, and we confirmed that informed consents had been obtained from all participants. If the responders feel that the survey has a negative impact on their work or life, they have the right to withdraw from the survey at any time.

3. Results

3.1. General Situation

A total of 576 questionnaires were collected, among which, 48 incomplete questionnaires were excluded and 528 were valid. The response rate was 96% and effective rate was 91.67%. A majority of respondents were from hospital ($n=464$, 87.87%). Most respondents were under 40 ($n=414$, 78.41%) (Table 1). Among the respondents, 128 held senior professional titles, accounting for 24.34%, 154 intermediate titles, 29.17%, 146 junior titles, 27.65%, and 100 were ungraded, 18.94% (Figure 1, Table 1).

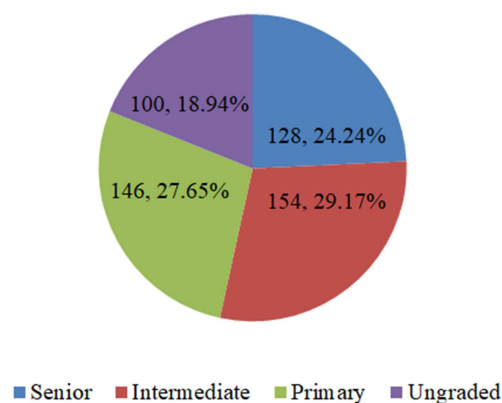

Figure 1. Professional Title Distribution of dentists.

Table 1. Characteristics of respondents.

		N=528	%
Hospital	General hospital	256	48.48
	Stomatological Hospital	208	39.39
	Clinic	64	12.12
Age	≤ 30	236	44.7
	31-40	178	33.71
	41-50	96	18.18
	> 50	18	3.14
Title	Senior title	128	24.24
	Intermediate title	154	29.17
	Primary	146	27.65
	Ungraded	100	18.94

3.2. Cognitive Situation of Gargle Types

Gargles are mainly used in the treatment of the periodontal disease and oral mucosal disease, and in the prevention of caries. 400 dentists knew a lot about the types of gargles for treating the periodontal disease, accounting for 75.76%, followed by 80 dentists who knew little about the types of gargles for treating the oral mucosal disease and preventing the caries, accounting for 15.15%. There was no statistical significance in the perception of gargle types among dentists with different professional titles ($P>0.05$) (Table 2).

Table 2. Cognition of gargle types by dentists with different professional titles.

Gargle types	Senior (n=128)	Intermediate (n=154)	Primary (n=146)	Ungraded (n=100)	Total (n=528)	χ^2	P
	Choice (%)	Choice (%)	Choice (%)	Choice (%)	Choice (%)		
Treatment of periodontal disease	100 (78.13)	122 (79.22)	110 (75.34)	68 (68.00)	400 (75.76)	4.69	0.20
Treatment of Mucosal Disease	42 (32.18)	54 (35.06)	52 (35.62)	34 (34.00)	182 (34.47)	0.28	0.97
Caries prevention	24 (18.75)	28 (18.18)	26 (17.81)	22 (22.00)	100 (18.94)	0.79	0.85
None of the above	16 (12.50)	20 (12.99)	26 (17.81)	18 (18.00)	80 (15.15)	2.69	0.44

3.3. Concerns Situation About Drug Resistance of Gargles

Among the 528 dentists, 256 claimed to have paid attention to the drug resistance of gargle, accounting for 48.48%, whereas 272 claimed to have not paid attention to it, accounting for 51.52%, the proportion of the former being lower than that of the latter. The proportion of senior dentists who were concerned about gargle resistance was 68.75%, which was higher than the proportion of the unconcerned dentists, standing at 31.25%, but the proportion of dentists

with intermediate, primary and ungraded titles who were concerned about gargle resistance was lower than that of those unconcerned dentists.

The proportion of senior dentists who were concerned about gargle resistance was significantly higher than that of those dentists with intermediate, primary and undetermined dentists ($P<0.01$). There was no statistical significance in the proportion among the latter three groups of the dentists regarding gargle resistance ($P>0.05$) (Table 3).

Table 3. Concerns of dentists with different professional titles on gargle resistance.

Attention	Senior (%)	Intermediate (%)	Primary (%)	Ungraded (%)	Total (%)	χ^2	P
concerned	88 (68.75)	64 (41.56)*	62 (42.47)*	42 (42.00)*	256 (48.48)	27.81	<0.01
Unconcerned	40 (31.25)	90 (58.44)	84 (57.53)	58 (58.00)	272 (51.52)		
Total	128 (24.24)	154 (29.17)	146 (27.65)	100 (18.94)	528		

Note: *: Compared with senior dentists, $P<0.05$.

3.4. Cognition of Adverse Reactions of Gargle

The most commonly used Compound Chlorhexidine Gargle was selected to investigate the cognition of dentists on the adverse reactions of gargles. The results showed that, as for the adverse reactions, the number of dentists who were aware of tooth staining, tongue coating yellow and taste changes were relatively higher, accounting for 51.52%, 43.18% and 41.67% respectively, and the awareness rate of other adverse reactions was lower than 25%. There were 46 dentists who chose "no adverse reaction" and 172 dentists who chose

"unclear", accounting for 8.71% and 32.58% respectively.

The awareness of "tooth staining" among senior dentists was significantly higher than that among intermediate, primary and ungraded dentists ($P<0.05$). As for "taste change", the awareness of ungraded dentists was significantly lower than that of senior, intermediate and junior dentists ($P<0.05$). The awareness of "taste change" among primary dentists was lower than that of senior dentists ($P<0.05$). As for other adverse reactions, there was no statistical significance among dentists with different professional titles ($P>0.05$) (Table 4).

Table 4. The perception of adverse reactions of gargles among dentists with different professional titles.

Adverse reaction	Senior (n=128)	Intermediate (n=154)	Primary (n=146)	Ungraded (n=100)	Total (n=528)	χ^2	P
	Choice (%)	Choice (%)	Choice (%)	Choice (%)	Choice (%)		
Tooth staining	80 (62.50)	72 (46.75)*	74 (50.68)*	46 (46.00)*	272 (51.52)	8.84	0.03
Yellowing of tongue coating	54 (42.19)	64 (41.56)	66 (45.21)	44 (44.00)	228 (43.18)	0.49	0.92
Dysgeusia	64 (50.00)	66 (42.86)	60 (41.10)	30 (30.00) *# Δ	220 (41.67)	45.25	<0.01
Dry	30 (23.44)	24 (15.58)	40 (27.40)	24 (24.00)	118 (22.35)	6.45	0.09
Metallic odor in oral cavity	24 (18.75)	20 (12.99)	28 (19.18)	20 (20.00)	92 (17.42)	3.04	0.39
Superficial debris of mucosa	14 (10.94)	16 (10.39)	6 (4.11)	12 (12.00)	48 (9.09)	6.25	0.10
Allergic reaction	38 (29.69)	44 (28.57)	24 (16.44)	20 (20.00)	126 (23.86)	0.36	0.55
No adverse reaction	6 (4.69)	12 (7.79)	14 (9.59)	14 (14.00)	46 (8.71)	6.16	0.10
Unclear	36 (28.13)	44 (28.57)	54 (36.99)	38 (38.00)	172 (32.58)	4.91	0.18

Note: *: Compared with senior dentists, $P<0.05$; #: Compared with intermediate dentists, $P<0.05$; Δ : Compared with junior dentists, $P<0.05$.

3.5. Cognition of Potential Risks of Long-term Frequent Use of Gargles

According to the survey, as for the most potential risk of frequent use of gargles for a long time, the number of dentists who chose "Oral flora disorder" was the highest among the respondents, accounting for 87.50%. 12.12% of dentists were

"unclear". Only 6.44% of dentists knew about "elevated blood pressure risk" and "increased risk of neck lymphoma".

Dentists with ungraded professional titles had a poorer understanding of risks. And the proportion of dentists who chose "unclear" was significantly higher than that of dentists with the other three professional titles ($P<0.05$). As for "oral

flora disorder", the perception of dentists with ungraded professional titles was significantly lower than that of dentists with senior, intermediate and junior professional titles ($P<0.05$). As for other risks, there was no statistical

significance in the perception of dentists with different professional titles (Fisher exact probability method, $P>0.05$) (Table 5).

Table 5. Cognition of potential risks of gargle by dentists with different professional titles.

Potential risks	Senior (n=128)	Intermediate (n=154)	Primary (n=146)	Ungraded (n=100)	Total (n=528)	χ^2	P
	Choice (%)	Choice (%)	Choice (%)	Choice (%)	Choice (%)		
Oral flora disorder	116 (90.63)	138 (89.61)	134 (91.78)	74 (74.00)*# Δ	462 (87.50)	20.88	<0.01
Increasing blood pressure risk	4 (3.13)	6 (3.90)	6 (4.11)	4 (4.00)	20 (3.79)	0.32	0.98
Increased risk of neck lymphoma	4 (3.13)	2 (1.30)	6 (4.11)	2 (2.00)	14 (2.65)	2.49	0.47
Unclear	8 (6.25)	20 (12.99)	12 (8.22)	24 (24.00)*# Δ	64 (12.12)	19.58	<0.01

Note: *: Compared with senior dentists, $P<0.05$; #: Compared with intermediate dentists, $P<0.05$; Δ : Compared with junior dentists, $P<0.05$.

3.6. Cognition of the Anti-Candida Albicans Effect of Gargles

As for compound chlorhexidine gargle, cetylpyridinium chloride gargle and povidone gargle, 7.58% of the dentists were not sure whether they had the effect of anti-Candida albicans. Among the three gargles, only 54.92% of the dentists had a relatively high awareness of the effect of compound chlorhexidine gargle.

Compared with senior professional dentists, intermediate and junior professional dentists had a higher awareness of the effect of compound chlorhexidine gargle and cetylpyridinium chloride gargle on Candida albicans ($P<0.01$). There was no statistical significance in the difference in cognition of povidone gargle against Candida albicans among all groups ($P>0.05$) (Table 6).

Table 6. Cognition of the anti-Candida albicans effect of gargle by dentists with different professional titles.

Gargle types	Senior (n=128)	Intermediate (n=154)	Primary (n=146)	Ungraded (n=100)	Total (n=528)	χ^2	P
	Choice (%)	Choice (%)	Choice (%)	Choice (%)	Choice (%)		
Compound chlorhexidine gargle	56 (43.75)	94 (61.04)*	92 (63.01)*	48 (48.00)	290 (54.92)	14.58	<0.01
Cetylpyridinium chloride gargle	24 (18.75)	52 (33.77)*	56 (38.36)*	24 (24.00)	156 (29.55)	15.41	<0.01
Povidone gargle	24 (18.75)	18 (11.69)	28 (19.18)	12 (12.00)	82 (15.53)	5.18	0.16
Unclear	8 (6.25)	8 (5.19)	12 (8.22)	12 (12.00)	40 (7.58)	4.45	0.22

Note: *: Compared with senior dentists, $P<0.05$.

4. Discussions and Conclusion

It is self-evident that the rational use of mouthwash, an auxiliary drug in oral clinic, is important. The premise of rational use is that dentists have a comprehensive understanding of gargles. One-sided understanding will inevitably lead to wrong selection of indications, increased incidence of drug resistance, adverse reactions and so on. Therefore, this study has a strong practical significance in promoting dentists to learn the theory of gargles and enhancing the scientificization of clinical medication of gargles through the investigation of dentists' perception of them.

There are wide varieties of gargles, including antibiotics, surfactants, traditional Chinese medicines and a few ethnic herbs. As far as their functions are concerned, gargles can prevent periodontal diseases, oral ulcers, caries, etc. There are prescriptions and non-prescriptions as for the usage [5-11]. The mouth rinses for periodontal disease, oral mucosal disease and caries prevention types listed in this survey are more common gargles. From the survey results, periodontal disease treatment gargle is the most familiar to dentists. According to the results of the fourth national oral health epidemiological survey, the periodontal health rates of the 35-44 age group,

55-64 age group and 65-74 age group in China are only 9.1%, 5.0% and 9.3% [12]. The national periodontal problems are aggravating, which inevitably leads to the increase of prescription rate of periodontal treatment gargles, and dentists have a relatively high understanding of it. However, we should also clearly see that 15.15% of the dentists do not understand all kinds of gargles. These dentists have a large blindness in the prescription of gargles, and it is even more difficult to scientifically and reasonably guide patients how to use gargles. In addition, there was no statistical significance among the dentists with different professional titles ($P>0.05$), which indicates that dentists do not have the corresponding enhancement of theoretical knowledge related to gargles with the growth of their qualifications in clinical work.

Resistance of bacteria to antibiotics is a major issue in clinical medicine in recent years, and the level of bacterial resistance is increasing [10, 13-15]. At present, almost all bacteria can acquire different resistance genes, and each antibiotic can be resisted and destroyed by some bacteria to varying degrees [16]. With the increasing use of antibiotics, most strains may show resistance to more than one antibiotic. Anaerobic bacteria in oral and maxillofacial infections have a high resistance rate to metronidazole [17]. As a prescription antibiotic, gargles also have the risk of drug resistance. For

instance, the most commonly used compound chlorhexidine gargle in oral clinic contains metronidazole, which may lead to bacterial resistance if it is improperly used. Dentists should have a clear understanding of the risk. However, the survey showed that 51.52% of dentists did not pay attention to the problem of gargles resistance and only senior dentists paid a little higher attention to gargles resistance, which only accounted for 68.75%. Literature researches were done with the keywords "gargles" or "mouthwash" or "mouth rinse", "drug resistance", and no relevant research reports or literatures were retrieved. From a subjective point of view, the dentists did not take the initiative to pay attention to the problem of gargle resistance. Whereas objectively, there is little information about gargles resistance, so it is difficult for dentists to obtain it.

Different gargles have different adverse reactions, which are usually marked on the instructions. For example, for the most commonly used compound chlorhexidine gargle, adverse reactions include tooth staining, yellowing of tongue coating, taste changes, etc. In addition, other side effects, such as dry mouth, astringent mouth, numbness of upper lip, itching of lips, slight tingling of oral mucosa and so on, may be caused by compound chlorhexidine gargle when used locally in the mouth because metronidazole is an effective component of it [18]. Besides, Lei Zhaobao and others considered that adverse reactions still include contact dermatitis and serious cases which can produce anaphylactic shock or even sudden death [19, 20]. Other gargles may also have these adverse reactions such as cetylpyridinium chloride gargle, whose main active ingredient is cetylpyridinium chloride. Although the adverse reactions labeled in the instructions are not clear, occasional taste disorders have been reported. The mechanism may be related to drug-induced zinc deficiency in the body, its own taste, damages to taste cells or taste bud centers, changes in chemical composition of saliva and mucus and the sensory information process of taste [21, 22]. The survey took compound chlorhexidine gargle as an example and some adverse reactions in the manual and literature were listed to give dentists a choice. The results showed that the knowledge rate of dentists on tooth coloring, tongue coating yellow and taste changes was relatively high, but only accounting for 51.25%, 43.18%, and 41.67%, respectively. Professional dentists at all levels do not have a comprehensive understanding of adverse reactions, few dentists made the right choice, and senior professional dentists are no better than other professional titles. It is worth noting that 218 people choose "no adverse reactions" and "unclear", which means that about 41.29% of the dentists had wrong knowledge or did not know about the adverse reactions of gargles, and among the dentists who did not choose the two items, there were still cognitive incompleteness. The accuracy and comprehensiveness of cognition are worrying. It is suggested that dentists at all levels should read the instructions carefully and strengthen literature reading.

Gargle will produce some side effects if it is used frequently for a long time. Therefore, it should be used under the guidance of dentists, and cannot be used for a long time. There

is normal flora in healthy oral cavity, and long-term use of gargles with bactericidal effect will lead to oral flora imbalance. Some studies have found that the use of anti-bacterial gargles can destroy oral flora and cause stress reaction, which can increase blood pressure, and has the potential to bring adverse cardiovascular diseases to healthy population [23, 24]. Studies have also shown that frequent use of gargle over a long period of time increases the potential risk of head and neck cancer [25]. Dentists' attentions are infrequently paid to this regard, most of which is limited to flora imbalance, and little is paid to other rare side effects. Even 12.12% of dentists do not know what potential adverse effects the frequent use of gargles will bring to patients. Although these conclusions need to be further studied and confirmed by evidence-based medicine, dentists should pay attention to the latest research trends of gargles.

Candida albicans is one of the most common symbiotic bacteria in oral cavity. With the application of antibiotics and the development of radiation medicine, the normal flora of oral cavity is imbalanced and *Candida albicans* multiplies in large numbers and causes disease [26-28]. Some gargles have scavenging effect on *Candida albicans*. Some studies have shown that compound chlorhexidine gargle and 0.5% povidone iodine gargle have the same bacteriostatic effect on *Candida albicans*, but significantly higher than 0.1% cetylpyridinium chloride gargle [29]. Some experiments also showed that 0.1% cetylpyridinium chloride gargle had a certain effect on oral *Candida* infection. There was no statistical significance between 0.1% cetylpyridinium chloride gargle and 1% povidone iodine in improving clinical symptoms and fungal clearance rate, or cetylpyridinium chloride gargle was slightly dominant [30, 31]. Regardless of the intensity of the action, compound chlorhexidine gargle, cetylpyridinium chloride gargle and povidone iodine gargle had the killing effect on *Candida albicans*. According to the questionnaire data, 54.92% of the dentists chose the compound chlorhexidine gargle, and nearly half of the dentists did not know it, while dentists had a very low understanding on the effect of killing *Candida albicans* of the other two mouthwashes, accounting for 7.58%. This shows that dentists have a one-sided understanding of how to kill *Candida albicans* with gargles.

In conclusion, the overall cognition of gargles by dentists in this province is not comprehensive or accurate, and the senior dentists do not show a higher level of cognition in general. This is a sample survey, but it can also be inferred that the overall perception of gargles among all dentists in China is not very optimistic. Error and one-sided cognition seriously affect the efficacy and safety of gargles. Based on that, we put forward the following suggestions to Chinese dentists and relevant departments, which may be of reference value to the rest of the world: 1. Basic and clinical researches on gargles should be further carried out, not only to study the mechanism and efficacy, but also to study drug resistance, adverse reactions and side effects, so as to continuously enrich the relevant theories of gargles. 2. The active learning of dentists should be further strengthened and literature reading should not be overlooked at any stage of their practice. They need to

continue to learn the various theories about gargles while keeping a close eye on the frontiers and trends of gargles researches. 3. Continuing medical education and other forms should be taken to promote dentists to learn the relevant theories of gargles, and it is necessary to realize the dynamic adjustment of the prescription right through the regular assessment of dentists.
