Abstract: In the presented paper, the effect of impeller geometric parameters on the performance of centrifugal pump has been investigated. This study was performed for different flow rates and rotational speeds, allowing to obtain the performance curve for the centrifugal pump. Three dimensional computational fluid dynamic simulation of the impeller and volute for a centrifugal pump has been performed using *ANSYS CFX* software (a high-performance computational fluid dynamics software tool that delivers reliable and accurate solutions). The pump has an outside impeller diameter of 205 mm, impeller outlet width of 16 mm, rotational speed 1450 rpm, seven impeller blade and a specific speed of 28. By increasing the impeller outer diameter and outlet width, both net head and power consumed are increased. In addition, it was noticed that the best efficiency point (BEP) was achieved at volume flow rate higher than design flow rate. The performed simulations indicated that; by changing the impeller outer diameter from 200 mm to 210 mm, the flow rate of BEP increases about by 14.7%. By changing the impeller outlet width from 14 mm to 18 mm, the flow rate of BEP increased by about 9%, and the efficiency of BEP reduced by approximately 0.5%. It was also noticed that, increasing the rotational speed will cause an increase in the net head and consumed power. An increase of 13.8% for the flow rate of BEP was observed when changing the rotational speed from 1400 rpm to 1500 rpm, with the same BEP.

Keywords: Centrifugal Pump, Impeller Diameter, Rotational Speed, Impeller Width

1. Introduction

In recent years, centrifugal pump have been increasingly utilized for various purposes, such as irrigation, water supply, steam power plants, oil refineries, air conditioning systems. Due to the vast application it is very important that centrifugal pump should work efficiently. Studies by the United States Department of Energy/Lawrence Berkeley National Laboratory and the European Commission show that more than 20% of the global motor electrical energy consumption is consumed by pumps. It was illustrated that pumps consume 22% of the industrial energy consumption, hence it presents an area which has great energy saving potential [1].

Based on the main pioneering researches on the centrifugal pump, the performance as a function of impeller geometry was investigated, and the obtained results were used for the design and selection of these pumps

Li investigated experimentally and numerically the effect of fluid viscosity on the performance of centrifugal oil pumps [2-7]. Based on his results, the high viscosity leads to rapid increase in the disc friction losses over outside of the impeller shroud and hub. The viscosity of fluid causes a flow reduction in the impeller and volute. Furthermore, Li found that there is a wide wake near the blade suction side of the centrifugal pump impeller. The optimum number was obtained of blades for the impeller when fluids with different viscosities are pumped.

Asuaje et al. studied numerically 3D flow solution by CFD

tools. Their method was based on the geometrical design and the performance analysis [8]. Their design tool took into account models and correlations resulting from experimental data dealing with many ranges of industrial centrifugal pumps which constitute a significant database.

Kergourlay *et al.* investigated numerically the effect of separated blades on the flow field of water in centrifugal pumps [9]. The presence of the splitters increases the head rise compared to the original impeller due to the increase of the impeller slip factor which helps conduction of the flow.

An experimental and numerical study was carried out by Shojaeefard *et al.* on the effect of the impeller blade's outlet angle of the centrifugal pump [10, 11]. When the blade outlet angle increases, the width of wake at the outlet of impeller decreases. This observed phenomenon causes an improvement in centrifugal pump performance when handling viscous fluids.

Grepas *et al.* investigated numerically the impeller blade design in centrifugal pumps by dynamic algorithm [12]. They obtained flow analysis was used to conduct parametric studies of the effect of some geometric parameters of a centrifugal pump impeller. Their results showed that their modifications could have a significant impact on its performance.

The numerical analysis carried out by Spence and Amaral-Teixeira investigated the geometrical variations on the pressure pulsations and performance characteristics of a centrifugal pump [13]. Their results concentrated on selected locations around the pump and provided the detailed information regarding the pressure pulsation close to the impeller outlet, in the volute and in the leakage flow region.

Cheah *et al.* investigated numerically the internal flow in a centrifugal pump having an impeller with six twisted blades by using a three-dimensional Navier-Stokes code with a standard $k-\varepsilon$ two-equation turbulence model [14]. A detailed analysis of the results at design load, (Q_{design}), and off-design conditions, ($Q=0.43 Q_{design}$ and $Q=1.45 Q_{design}$), were presented. Their results showed that the impeller passage flow at design point is quite smooth and follows the curvature of the blade. When operating at off-design load, the flow pattern has changed significantly from the well-behaved flow pattern at design load condition.

The performance of a centrifugal pump with a five blade impeller was numerically investigated by Guleren and Pinarbasi at low rotating speed of 890 rpm [15]. The $k-\varepsilon$ turbulence model has been used in computational used by Guleren. Flow characteristics were assumed to be stalled in the appropriate region of flow rate levels of 1.31–2.86 L/s. Being below design conditions, there is a consistent high-speed leakage flow in the gap between the impeller and the diffuser from the exit side of the diffuser to the beginning of the volute.

Asuaje *et al.* performed a 3D-CFD simulation of impeller and volute of a centrifugal pump using CFX code with a specific speed of 32 [16]. The flow simulation was carried out for several impeller blades and volute tongue relative

positions. The velocity and pressure field were calculated for different flow rates, allowing to obtain the radial thrust on the pump shaft.

Spalart-Allmaras on equation turbulence model has been used by Cui *et al.* to numerically investigate the effect of number of splitting blades on the flow characteristics using long, mid and short blades [17]. The relative velocity distribution, pressure distribution and static pressure rise at the design point were obtained for the regular impeller with only long blades and three complex impellers with long, mid or short blades.

Anagnostopoulos simulated 3D turbulent flow in a radial pump impeller for a constant rotational speed of 1500 rpm using standard $k-\varepsilon$ turbulence model [18]. A number of geometric variables are introduced for the parameterization of the impeller

geometry allowing also for easy design modifications. They presented the characteristic performance curves for the entire load range of the impeller are constructed, and their pattern is found reasonable and in agreement with theory.

Anagnostopoulos developed numerical methodology to simulate the turbulent flow in a 2D centrifugal pump impeller using the $k-\varepsilon$ turbulence model [19]. The predicted overall efficiency curve of the pump was found to agree very well with the corresponding experimental data. The developed numerical optimization algorithm was combined with the evaluation software in order to find the impeller geometry that maximizes the pump efficiency, using as free design variables the blade angles at the leading and the trailing edge.

The effect of various geometrical parameters on improving the performance of centrifugal pump was numerically investigated by Bacharoudis *et al.* [20]. It was concluded that, by increasing the blade angle, the performance curve becomes smoother and flatter for the whole range of the flow rates. When pump operated at nominal capacity, the gain in the head is more than 6% when the outlet blade angle increases from 20° to 50° .

Weidong *et al.* investigated numerically the effect of impeller outlet width on performance of deep well centrifugal pump [21]. The performance results indicated that the oversize impeller outlet width leads to poor pump performances and increasing shaft power. The proposed research enhances the theoretical basis of pump design to improve the performance and reduce the manufacturing cost of deep-well centrifugal pump.

Singh *et al.* investigated numerically the relationships among the impeller eye diameter, vane exit angle and width of the blade at exit [22]. Different pump models were studied by varying critical design parameters to different levels. Optimal pump design is formulated using Response surface method. The objective functions were defined as the total head and the total efficiency at the design flow-rate.

Zhou *et al.* studied numerically the optimization of geometric parameters of a centrifugal impeller [23]. The original pump was manufactured and tested in a centrifugal

pump test rig. Five main impeller geometric characteristics were chosen as the research target to carry out the orthogonal experiment. The best programs for pump efficiency and head were obtained through the variance analysis method. The results demonstrated that the impeller outlet width has the largest effect on both pump efficiency and head.

Mentzos et al. investigated numerically the complex internal flows in water pump impellers, thus facilitating the design of pumps [24]. The commercial three-dimensional Navier-Stokes code Fluent, with a standard $k-\varepsilon$ turbulence model was used to simulate the problem under examination. The calculation predicted the flow pattern and the pressure distribution in the untwisted blade passages and the overall performances and the head-capacity curve were discussed.

The current work is numerical investigates the effect of impeller geometry on the centrifugal pump performance.

2. Physical Model

Three-dimensional (3D) single-stage and single-suction centrifugal pump was employed. The centrifugal pump design parameters are as follows: flow rate $Q=52.5 \text{ m}^3/\text{h}$, head $H=12.75 \text{ m}$, rotating speed $N=1450 \text{ rpm}$, and specific speed $n_s=28$. Figure 1 shows the centrifugal pump main dimensions. Table 1 shows the main geometric parameters of the centrifugal pump.

Figure 1. Centrifugal pump main dimensions.

Table 1. Main geometric parameters of the centrifugal pump.

Parameter	Value
D_1	109 mm
D_2	205 mm
β_2	27°
b	16 mm
Z	7

3. Computational Model

3.1. Fundamental Equations

The fundamental equations are employed to describe the flow characteristics in the centrifugal pump, which

include two main parts: continuity equation and motion equation, corresponding with mass conservation law and momentum conservation law.

$$\frac{\partial \rho}{\partial t} + \frac{\partial (\rho u_i)}{\partial x_i} = 0 \quad (1)$$

$$\rho \frac{\partial u_i}{\partial t} + \rho u_j \frac{\partial u_i}{\partial x_j} = \rho f_i - \frac{\partial p}{\partial x_i} + \frac{\partial}{\partial x_j} \left[\mu \left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i} \right) \right] - \frac{2}{3} \frac{\partial}{\partial x_i} \left(\mu \frac{\partial u_j}{\partial x_j} \right) \quad (2)$$

Where: ρ = The fluid density

u = The fluid velocity

f_i = The body force

p = The pressure

μ = The fluid dynamic viscosity

3.2. Turbulence Model

RNG $K-\varepsilon$ turbulent model proposed by Yakhot and Orzag was employed to deal with turbulent flow [25]. In the centrifugal pump, the impeller is the rotating part whose rotation effects could be fully dealt by the turbulent dissipation rate (ε) equation in this turbulent model. On the other hand, the RNG $K-\varepsilon$ turbulent model has high-precision, which could guarantee the accuracy of the numerical results.

$$\frac{\partial (\rho k)}{\partial t} + \frac{\partial (\rho k u_i)}{\partial x_i} = \frac{\partial}{\partial x_j} \left[\alpha_k (\mu + \mu_t) \frac{\partial k}{\partial x_j} \right] + G_k + \rho \varepsilon \quad (3)$$

$$\frac{\partial (\rho \varepsilon)}{\partial t} + \frac{\partial (\rho \varepsilon u_i)}{\partial x_i} = C_{1\varepsilon} \frac{\varepsilon}{k} G_k C_{2\varepsilon} \rho \frac{\varepsilon^2}{k} + \frac{\partial}{\partial x_j} \left[\alpha_\varepsilon (\mu + \mu_t) \frac{\partial \varepsilon}{\partial x_j} \right] \quad (4)$$

$$\mu_t = \rho C_\mu \frac{k^2}{\varepsilon} \quad (5)$$

Where: k = The turbulent kinetic energy

ε = The turbulent dissipation rate

μ_t = The turbulent viscosity

G_k = The generation term of turbulent kinetic energy which is caused by the mean velocity gradient

$C_{1\varepsilon}, C_{2\varepsilon}, \alpha_k, \alpha_\varepsilon, C_\mu$ = Empirical coefficients

$$C_{1\varepsilon} = 1.42 \quad C_{2\varepsilon} = 1.68 \quad \alpha_k = 1.39 \quad \alpha_\varepsilon = 1.39 \quad C_\mu = 0.09$$

3.3. Mesh Characteristics

After determining the computational domain model, turbogrid was used to generate an unstructured tetrahedral meshing for all the computational domains. The reason of using unstructured mesh in current analysis is due to the complexity and irregular profile of the impeller and volute geometry. A localized refinement of mesh is used at regions close to volute tongue area, impeller blade leading and trailing edge in order to accurately capture the flow

field structure. This is because the flow field properties variation such as pressure and velocity at these regions are expected to be substantial. Figure 2 shows the meshes of the centrifugal impeller and the mesh assembly of the whole flow field.

Grid sensitivity test was performed using six mesh sizes of the to divide the grid of the model. The grid numbers are 280410, 410260, 512242, 614560, 718766, 810315 and 907472, were examined as indicated in Figure 3. The final mesh number used in the computational analysis in this paper was set to 810315.

Figure 2. Mesh sensitivity analysis.

Figure 3. Mesh of impeller and volute.

3.4. Boundary Conditions

Centrifugal pump impeller domain is considered as rotating frame of reference with a rotational speed. A standard $k-\varepsilon$ turbulence model has been activated in the model solver. Non slip boundary conditions have been imposed over the impeller blades, hub and shroud. Inlet static pressure and outlet mass flow rate are given based on flow rate as boundary conditions. Convergence precision of residuals is considered as 10^{-5} . Three dimensional incompressible Navier-Stokes equations are solved with Ansys-CFX Solver.

4. Results and Discussion

The developed numerical model is applied to reproduce the performance characteristic curves of the standard centrifugal pump. Different simulations were carried out for different flow rates changing from 30 to 64 m^3/h .

The computed curves are drawn in Figures 4, 5 and 6 for the original centrifugal pump with parameters 1450 rpm, Impeller outer diameter 205 mm, Impeller blade thickness 5mm, impeller outlet width of 16 mm, and impeller outlet blade angle 27° .

Figure 4 shows the $H-Q$ curve for the centrifugal pump. It is clear that for the centrifugal pump by increasing the volume flow rate the net fluid head is decreased.

Figure 5 illustrates the $P-Q$ curve for the centrifugal pump. It is clear that for the centrifugal pump by increasing the volume flow rate the power consumed by the centrifugal pump is increased.

Figure 6 depicts the $\eta-Q$ curve for the centrifugal pump. It is clear that that the maximum overall efficiency is about 70.1% and is achieved for $Q = 52.5 \text{ m}^3/\text{h}$.

The velocity contours in the pump are plotted in Figure 7 for the impeller and volute at design flow rate $Q_{\text{design}} = 52.5 \text{ m}^3/\text{h}$. The volute tongue zone presents a strong recirculation of the fluid particles at the gap between the volute tongue and the impeller periphery.

Figure 8 demonstrates the pressure distribution within the impeller and volute casing when the pump is operating at design flow rate $Q_{\text{design}} = 52.5 \text{ m}^3/\text{h}$. The pressure increases gradually along streamwise direction within impeller blade-to-blade passage and has higher pressure on pressure surface than suction surface for each plane. However, the developed pressure inside the impeller and volute is not so uniform. The isobar lines are not all perpendicular to the pressure side of the blade inside the impeller passage, this indicated that there is a potential of flow separation because of the pressure gradient effect.

Figure 4. $H-Q$ curve.

Figure 5. $P - Q$ curve.

Figure 7. Velocity distribution inside impeller and volute.

Figure 6. $\eta - Q$ curve.

Figure 8. Pressure distribution inside impeller and volute.

4.1. Effect of Impeller Diameter

In this section the effect of changing the impeller outer diameter on the centrifugal pump performance characteristic curves is introduced. The numerical simulation of the Centrifugal pump is carried out for different flow rates changing from 30 to 64 m³/h. The obtained performance curves are plotted for centrifugal pump with parameters; rotational speed 1450 rpm, Impeller blade thickness 5mm, impeller outlet width of 16 mm, and impeller outlet blade angle 27°. The impeller outer diameter has different values of 200, 205, 210 mm.

Figure 9 shows the $H - Q$ curve for the centrifugal pump. By increasing the volume flow rate, the net fluid head is decreased for the same impeller diameter. while, increasing the impeller outer diameter the net fluid head as well as the consumed power is increased.

Figure 10 shows the $P - Q$ curve for the centrifugal pump. It is noticed that by increasing the volume flow rate the power consumed by the centrifugal pump is increased for the same impeller diameter.

Figure 11 illustrates the $\eta - Q$ curve for the centrifugal pump. It is clear that that the best point efficiency is achieved for $Q_{design} = 52.5 \text{ m}^3/h$ for impeller diameter of 205mm. By increasing the impeller diameter the best point efficiency achieved at volume flow rate higher than Q_{design} . By increasing the impeller diameter the best efficiency point achieved at volume flow rate higher than Q_{design} . The flow rate and pump efficiency at BEP with different impeller diameter was summarized in Table 2. From 200 mm to 210 mm of impeller outlet diameter, the flow rate of BEP increased about by 14.7%, with the same BEP.

Table 2. Flow rate and efficiency at BEP for different impeller diameter.

Impeller Diameter (mm)	200	205	210
Flow Rate Q/Q_{design}	0.928	1	1.075
Efficiency, η %	70.10	70.10	70.10

Figure 9. $H - Q$ curve for different impeller diameter.

Figure 10. $P - Q$ curve for different impeller diameter.

Figure 11. $\eta - Q$ curve for different impeller diameter.

4.2. Effect of Rotational Speed

This section defines the effect of changing impeller rotational speed on the centrifugal pump performance characteristic curves. The computational analysis of Centrifugal pump is carried out for different flow rates changed from 30 to 64 m³/h. The computed curves are presented for centrifugal pump with parameters; impeller outer diameter 205 mm, Impeller blade thickness 5mm, impeller outlet width of 16 mm, and impeller outlet blade angle 27°. The impeller rotational speed has different values of 1400, 1450, 1500 rpm.

Figure 1 demonstrates the $H - Q$ curve for the centrifugal pump. For the defined centrifugal pump in this paper, by increasing the volume flow rate the net fluid head is decreased for the same rotational speed. By increasing the impeller rotational speed the net fluid head increases and the power consumed by the centrifugal pump is also increases.

Figure 13 shows the $P - Q$ curve for the centrifugal pump. It is clear that for the centrifugal pump by increasing the volume flow rate the power consumed by

the centrifugal pump is increased for the same impeller rotational speed..

Figure 14 depicts the $\eta - Q$ curve for the centrifugal pump. It is clear that the best point efficiency is achieved for $Q_{design} = 52.5 \text{ m}^3/\text{h}$ for impeller rotational speed of 1450 rpm. By increasing the impeller rotational speed the best point efficiency achieved at volume flow rate higher than Q_{design} . By increasing the impeller rotational speed the best point efficiency achieved at volume flow rate higher than Q_{design} . The flow rate and pump efficiency at BEP with different impeller rotational speed was summarized in Table 3. From 1400 rpm to 1500 rpm of impeller rotational speed, the flow rate of BEP increased about by 13.8%, and the same BEP.

Table 3. Flow rate and efficiency at BEP for different rotational speed.

impeller rotational speed (rpm)	1400	1450	1500
Flow Rate Q/Q_{design}	0.932	1	1.070
Efficiency, η %	70.10	0.10	70.10

Figure 12. $H - Q$ curve for different impeller rotational speed.

Figure 13. $P - Q$ curve for different impeller rotational speed.

Figure 14. $\eta - Q$ curve for different impeller rotational speed.

4.3. Effect of Impeller Outlet Width

In this section study the effect of Impeller outlet width on the centrifugal pump performance characteristic curves. Centrifugal pump is solved for different flow rates changing from 30 to 64 m^3/h . The obtained performance curves are plotted for centrifugal pump with parameters; impeller outer diameter 205 mm, Impeller rotational speed, Impeller blade thickness 5mm, and impeller outlet blade angle 27° . The impeller outlet width has different values of 14, 16, 18 mm.

Figure 15 presents the $H - Q$ curve for the centrifugal pump. It is clear that for the centrifugal pump by increasing the volume flow rate the net fluid head is decreased for the same impeller outlet width. By increasing the impeller outlet width the net fluid head is increased and the power consumed is also increased.

Figure 16 shows the $P - Q$ curve for the centrifugal pump. It is clear that the power consumed by the centrifugal pump is increased, by increasing the volume flow rate for the same impeller outlet width..

Figure 17 defines the $\eta - Q$ curve for the centrifugal pump. It is clear that the best point efficiency is achieved for $Q_{design} = 52.5 \text{ m}^3/\text{h}$ for impeller outlet width of 16mm. By increasing the impeller outlet width the best point efficiency achieved at volume flow rate higher than Q_{design} . By decreasing the impeller outlet width the best point efficiency achieved at volume flow rate lower than Q_{design} . The flow rate and pump efficiency at BEP with different impeller outlet width was summarized in Table 4. From 14 mm to 18 mm of impeller outlet width, the flow rate of BEP increased about by 9%, and the efficiency of BEP reduced by 0.5% approximately.

Table 4. Flow rate and efficiency at BEP for different blade width.

Blade outlet width (mm)	14	16	18
Flow Rate Q/Q_{design}	0.96	1	1.05
Efficiency, η %	70.30	70.10	69.80

Figure 15. $H - Q$ curve for different impeller outlet width.

Figure 16. $P - Q$ curve for different impeller outlet width.

Figure 17. $\eta - Q$ curve for different impeller outlet width.

5. Conclusions

From the numerical results and discussions for the effects of impeller parameters on the centrifugal pump performance, the following conclusions are drawn:

1. Both net fluid head and power consumed are increased with the increasing of impeller outer diameter.

2. By increasing the impeller diameter the best efficiency point achieved at volume flow rate higher than Q_{design} . When impeller diameter changes from 200 mm to 210 mm, the flow rate of BEP increased about by 14.7%, with the same BEP.

3. Both net fluid head and power consumed are increased with the increasing of the impeller rotational speed.

4. By increasing the impeller rotational speed the best point efficiency achieved at volume flow rate higher than Q_{design} . When impeller rotational speed changes from 1400 rpm to 1500 rpm, the flow rate of BEP increased about by 13.8%, and the same BEP.

5. Both net fluid head and power consumed are increased with the increasing of the impeller outlet width.

6. By increasing the impeller outlet width the best point efficiency achieved at volume flow rate higher than Q_{design} . When impeller outlet width changes from 14 mm to 18 mm, the flow rate of BEP increased about by 9%, and the efficiency of BEP reduced by 0.5% approximately.

Notation

b	Impeller width (m)
BEP	Best Efficiency Point
CFD	Computational Fluid Dynamic
D_1	Impeller inlet diameter (m)
D_2	Impeller outlet diameter (m)
H	Net fluid head
K	Turbulent kinetic energy
N	Rotational Speed (rpm)
n_s	Specific speed
Q	Volume flow rate (m^3/h)
Z	Number of blades
μ_t	Turbulent viscosity (Pa.s)
μ	Viscosity (Pa.s)
ε	Turbulent dissipation rate
β_1	Inlet blade angle ($^\circ$)
β_2	Outlet blade angle ($^\circ$)
