Abstract: In order to obtain Stress distribution and damage law of Steeply inclined working face floor, this paper combined elastic-plastic mechanics theory to improve model of the half-infinite body model, and the three-dimensional half-infinite body model was established which comprehensively considered the stress characteristics in the strike and inclined directions of the working face, and the iterative formula of vertical stress in floors was calculated. Meanwhile, the three-dimensional stress distributions in floors with different depths were calculated by Software-MATHCAD and SUFER. The numerical simulation was applied to simulate no supporting condition and temporary supporting with Cement Based Grouting Material condition in fully-mechanized coal caving face of steeply inclined coal seam and obtained the corresponding plastic damage zone. According to the empirical formula calculated formula floor damage depth of 10.4m, and the application of cement grouting material was carried out on the floor, temporary support, in the working face, the lower floor heave amount reduced 28.7%, in the working face, the upper floor heave amount reduced 22.4%, and the supporting method can effectively control the floor damage. The results show that provided a theoretical basis for the floor management of steep coal seam working face.

Keywords: Steeply Inclined Working Face, Stress Distribution, Numerical Modeling, The Grouting Support

1. Introduction

The steep coal seam mining technology development level is far lower than gently inclined seam, at the same time there are a series of technical problems unresolved. Caused by coal mining stress distribution of the space around the change and to the bottom of deep, finally appear different coal floor damage [1]. In the process of mining of deeply inclined coal seam and floor strata is an important part of face space support system. Master the destruction rule of working face floor stress distribution characteristics and floor strata is the realization of steep coal seam floor security management and guarantee the important premise of mine safety production [2].

Study steeply inclined working face floor damage, many scholars only analyzes the destruction rule of working load of base plate toward the direction [3-11], ignoring the inclination direction on steep face the influence of load. Based on elastic-plastic mechanics theory and theory of three-dimensional semi-infinite body [12], steep face slab stress mechanics model is established, further concluded that

the floor strata stress formula. Steeply inclined coal face slab are analysed under the joint action of trends and tendencies load state of three-dimensional stress distribution and failure regularity, and determined the floor damage depth and bottom supporting method, through the above research is of great significance to the mine working face floor management, to ensure production safety and efficiency of the working face.

2. Working Face Floor Stress Distribution Research

According to the knowledge of mine pressure and elastic mechanics and steep seam occurrence particularity, the half-space model was improved to tilt the three-dimensional half-space model, as shown in figure 1, $\alpha \geq 45^\circ$. The effect of the model by F concentrated force, and the model by the normal component of F_1 , along the Y axis orientation of component F_2 . Due to the large face steep dip Angle of the special reason, tendency of component is more and more big,

the rock mass by the force of law to the tendency to component and component interaction (as shown in figure 1).

Figure 1. Diagram of the concentrated force in the three-dimensional semi-infinite space.

As A bit of $M(x, y, z)$ vertical stress in the σ_z floor rock mass for the law to the component and the tendency of component the result of joint action. The role of discussion method to the first component F_1 :

$$\sigma_{z1} = \frac{3Fz^3}{2\pi(x^2 + y^2 + z^2)^{5/2}} \quad (1)$$

Within an arbitrary partition, stress coefficient in the X, Y axis direction changes as shown in formula (2).

$$q(x) = q(\xi) = \frac{\eta - \eta_1}{\eta_2 - \eta_1} (\xi_2 - \xi_1) + \xi_1 \quad (2)$$

$$p(y) = p(\eta) = \frac{\xi - \xi_1}{\xi_2 - \xi_1} (\eta_2 - \eta_1) + \eta_1 \quad (3)$$

a. Face towards the direction of stress distribution

b. The stress distribution of face tilt direction

Figure 2. Changes of floor stress distribution.

All partitions in the floor strata under the influence of the load stress is:

$$\sigma_z(x, y, z) = \sum_{i=1, j=1}^9 \sigma_z^{i,j}(x, y, z) \quad (7)$$

Type: ξ , η , respectively the X, Y direction stress coefficient, so the first j partition load stress affect the action of the floor is:

$$\sigma_{z1}^{(j)}(x, y, z) = -\frac{3z^3}{2\pi} \int_{\xi_{1j}}^{\xi_{2j}} \int_{\eta_{1j}}^{\eta_{2j}} \left[\frac{\eta - \eta_{1j}}{\eta_{2j} - \eta_{1j}} (\xi_{2j} - \xi_{1j}) + \xi_{1j} \right] + \left[\frac{\xi - \xi_{1j}}{\xi_{2j} - \xi_{1j}} (\eta_{2j} - \eta_{1j}) + \eta_{1j} \right] \frac{d\eta d\xi}{[(x - \xi)^2 + (y - \eta)^2 + z^2]^{5/2}} \quad (4)$$

Similarly, discuss the tendency of component F_2 function:

$$\sigma_{z2} = \frac{F_x z^2}{\pi(x^2 + y^2 + z^2)^{5/2}} \quad (5)$$

The first i partition load stress affect the action of the floor is:

$$\sigma_{z2}^{(i)}(x, y, z) = -\frac{3z^3}{2\pi} \int_{\xi_{1i}}^{\xi_{2i}} \int_{\eta_{1i}}^{\eta_{2i}} \left[\frac{\eta - \eta_{1i}}{\eta_{2i} - \eta_{1i}} (\xi_{2i} - \xi_{1i}) + \xi_{1i} \right] + \left[\frac{\xi - \xi_{1i}}{\xi_{2i} - \xi_{1i}} (\eta_{2i} - \eta_{1i}) + \eta_{1i} \right] \frac{d\eta d\xi}{[(x - \xi)^2 + (y - \eta)^2 + z^2]^{5/2}} \quad (6)$$

To simplify the will base on the load, as shown in figure 2 (working in $x = 90m$ place, inclined position from $y = 30m$ to $y = 160m$).

Figure 3. The three-dimensional of contours of the stress coefficient of the floor.

Using MATHCAD software to calculate the coefficient of different depth of floor stress and combining Sufer charting software, it is concluded that the three dimensional state under different depth of floor stress coefficient contour stereogram, Z axis stress coefficient, Y axis working face, the X-axis represents the working face. As shown in figure 3.

By figure 3 available:

(1) Floor below 10m, 25m in depth of the maximum stress coefficient were 1.68, 1.17. Maximum stress coefficient at coal face in front of the 0~23m, 0~29m range. On both sides of the working face and goaf and both sides have different degree of stress concentration, the goaf under stress is greater than the upper side. When distance floor below 40m in the depth of the stress concentration area basically does not exist, but there are a range of unloading zones, the minimum stress coefficient of 0.421;

(2) With bottom depth increase, the three-dimensional state of floor strata stress coefficient of each isoline stereogram funnel in high stress area increases gradually, but the stress coefficient decreases, eventually tend to 1; Low stress area decreases, but the stress coefficient is increased gradually, eventually tend to be 1.

3. Face Plate Destruction In-depth Analysis

Due to coal mining floor rock mass stress secondary distribution further causes damage on the floor. According to the floor rock mass stress distribution, take along the working direction of the tilt section as the calculation section [13], According to the principle of Saint Venant, about the way of working face tendency of abutment pressure static equivalent force system replace, combining with Mohr-Coulomb criteria for working face floor rock mass maximum damage depth h [14-15].

$$h = \frac{(n+1)H}{2\pi} \left(\frac{2\sqrt{k}}{k-1} - \arccos \frac{k-1}{k+1} \right) - \frac{R_c}{\gamma(k-1)} \quad (8)$$

Type: n is the maximum stress concentration factor; H is mining depth; $k = (1 + \sin \phi) / (1 - \sin \phi)$, ϕ is internal friction Angle of rock mass; R_c is unidirectional compressive strength of rock mass; γ is rock mass density.

Mine 3232 (3) working face maximum mining depth is 495m, the floor rock mass unidirectional compressive strength is 2.9MPa, internal friction Angle of rock mass is 42°, rock mass density is 0.025MN/m³, the calculated formula floor damage depth of 10.4m.

4. The Numerical Simulation

4.1. The Establishment of the Model

Due in the process of mining steep stress distribution and plastic damage, using FLAC3D built along the mine 3232 (3) working face toward the direction of advance of FLAC3D numerical model. Face to the length of 980 m, length of 124 m, the total height is 520m, an average of 495 m buried deeply. To illustrate the overburden force of the model, basic roof applying vertical load 12.5MPa. In the model the main research floor rock mass affected by the process of working face advancing and produce the plastic failure mechanism. Mechanical characteristic parameters of coal seam roof and floor are shown in table 1.

Table 1. Characteristic parameters of coal seam roof and floor mechanics.

The lithology	Density/(kg·m ⁻³)	Bulk modulus (GPa)	Modulus of rigidity (GPa)	Angle of internal friction (°)	Cohesive strength (MPa)	Tensile strength (MPa)
Medium coarse sandstone	2500	8.2	7.2	30	3.8	4.2
Fine sandstone	2400	7.8	7.1	31	3.9	4.1
Mudstone	2200	5.9	5.2	33	2.1	1.4
Coal	1470	2.2	2.0	28	1.8	0.8
Mudstone	2200	5.9	5.2	33	2.1	1.4
Siltstone	2530	8.3	7.4	35	3.1	3.4
Post stone	2500	10.6	9.0	35	4.5	3.8
Medium coarse sandstone	2510	8.3	7.4	31	3.6	3.2

4.2. Analysis of Surrounding Rock Floor Without Supporting Condition

The plastic zone along the working face sloping direction as shown in figure 4, By figure 4a, the distribution of lateral abutment pressure caused by the plastic on both ends of the working face and level of working face are similar, but different on both ends of the plastic zone damage, on both sides of the mass media has a stress concentration. After coal extraction, face the floor rock mass unloading zone and form a

larger plastic damage area in floor rock mass, the plastic damage area show the middle and lower slightly larger than the upper asymmetry, in the working face was described, and the lower plastic damage more serious. The figure 5a shows that steep face plate of displacement is vertical displacement and horizontal displacement of the fitting, the show floor and floor heave, plastic deformation and destruction in serious area of floor heave of bottom slip, should increase the floor rock mass strength, increase the cohesion of rock mass, to prevent the destruction of the bottom slip to support, coal winning machine equipment damage.

b. After supporting

Figure 4. Working face floor support before and after the distribution of plastic zone.

a. Support before

b. After supporting

Figure 5. Before and after the working face floor support displacement.

4.3. The Scheme Determination of Floor Grouting

Accord with Mohr-Coulomb criterion floor rock mass:

$$\tau = c + \sigma_n \tan \phi \quad (9)$$

Type: c is the cohesion of rock mass; σ_n is the normal stress shearing surface; ϕ is the internal friction Angle of rock mass. In order to prevent steep face plate destruction to the harm of production equipment and affect production safety. Coal mine grouting reinforcement method, increase the cohesion of c rock to improve the overall floor rock mass strength further control bottom plastic damage.

Theoretical calculation of the maximum damage depth of 10.4m floor and floor unsupported state numerical simulation

analysis on motherboard damage depth of 11.2m, the gap between the two groups of damage depth of 0.8 m belongs to within a reasonable range. Considering the situation working face, the injection of cement grouting reinforcement material site selection in the coal wall slab depth of 10.4m.

4.4. Floor Bolting After the Analysis of the Surrounding Rock

After working face according to the requirements for supporting, again using numerical simulation software to calculate and compared with without supporting conditions. According to figure 4b, the damage zone and the bottom floor plastic damage depth is reduced, after this case bottom support, increase the cohesion of rock mass and the strength of the rock mass. At the same time, under the influence of mining stress difference before and after mining reduced, this for unloading area floor damage under effective control; By figure 5b, Coal floor in vertical and horizontal direction of fitting displacement decrease obviously, this kind of situation that floor damage amount is reduced, by supporting amount of drum at the bottom of the 322.5mm to 260.5mm.

5. Field Application Effect

Mine 3232 (3) working face length of 124 m, the mine coal seam dip Angle 45° on average. As shown in figure 6, 7, during working face floor, floor in accordance with the plan calls for injection after grouting reinforcement material, middle and lower support before the sole drum quantity is 330.5mm, after supporting is 235.5mm, floor heave amount reduced 28.7%. Amount of working face in the middle and upper part of the sole drum is 275mm, after supporting is 213.5mm, floor heave amount reduced 22.4%.

Figure 6. Before and after the working face Middle and lower part floor support displacement.

Figure 7. Before and after the working face Middle and upper part floor support displacement.

6. Conclusion

(1) Through the establishment of steeply inclined coal face slab stress model, it is concluded that the three-dimensional state of face slab vertical stress contour stereogram, Face slab depth can be drawn from the high stress area increases gradually, but the stress coefficient decreases, and eventually tend to 1; Although the stereogram display low stress area decreases, but the stress coefficient is gradually increases and eventually tend to be 1.

(2) According to the principle of Saint Venant, Mohr-Coulomb standards, it is concluded that the mine 3232 (3) working face slab maximum damage depth of 10.4m. And deep in the bottom of 10.4 m for grouting material support, this kind of supporting method can effectively control the floor damage and slippage and makes the floor damage amount is reduced, and from supporting amount of floor heave at the bottom of the 322.5mm to 260.5mm.
