Abstract: Background: *Acinetobacter baumanii* is often referred to as the “Gram-negative methicillin-resistant *Staphylococcus aureus*”, because it is frequently resistant to antibiotics. Clonal outbreaks of carbapenem-resistant and OXA-23-producing *A. baumannii* have been reported worldwide. Aim: The goal of this study was to promote the phenomenon of disbalance in endemic hospital ECO system which included increase of carbapenemase-resistant *Acinetobacter baumanii* on account of reduction of MRSA rate in surgical ICU and it’s clonal relatedness as well as the specific precautions. Material nad Methods: Computer database from 1994 – 2012 from surgical ICU patients in the Clinical Center Skopje was used as basic material for this study. Comparative study indicated 2007/8 as a break point period in which almost a twofold decrease of MRSA rates (from over 80% to 45%) versus increased rates of *Acinetobacter* (from 29% to 40%) was observed. In 2011 the very first eight strains of carbapenem resistant (resistant to imipenem and meropenem) *A. baumannii*, were observed. Disc diffusion and VITEK were used for antibiotic susceptibility testing. Resultes: Three distinct strains were detected by PFGE and were designated as UKIM01AC-1 (5 strains), UKIM01AC-2 (two strains) and 642/2 (one strain). UKIM01AC-1 representatives were PCR positive for bla (OXA-23-like), in addition to the bla (OXA- 51-like) gene which is intrinsic in *Acinetobacter baumannii*. All isolated strains belonged to European clone II lineage. Conclusion: This clone dispersed very fast in 2012 and achieved the rate of 61.9%. This implicated changes in infection control precautions.

Keywords: *Acinetobacter*, Carbapenem Resistance, Clonal Distribution, Endemic ECO System

1. Background

*Acinetobacter baumanii* is often referred to as the “Gram-negative methicillin-resistant *Staphylococcus aureus*”, because it is frequently resistant to antibiotics. [1,2,3]

The epidemiologies of the two microbial species are very different and therefore, it is questionable whether the same control measures can be applied to the two pathogens. MRSA is primarily spread from person-to-person, whereas *Acinetobacter* infections often have an environmental source or reservoir. Allen and Green concluded that widespread aerial dissemination of *Acinetobacter* spp. occurred and this partly contributed to the environmental reservoir.

Referring to Allen and Green’s study, Das et al. [4] hypothesised that heavily contaminated bed curtains, when moved would promote the airborne spread of *Acinetobacter* spp. Weernink et al. [5] investigated the airborne dispersal of *Acinetobacter baumanii* from patient’s pillows. Using settle plates they found aerial dissemination from feather pillows, but not from synthetic pillows.

Numerous investigators have demonstrated the relative ease with which the clinical environment can become contaminated with pathogenic *Acinetobacter* species.

Dissemination by airborne or other routes can seed environmental reservoirs which either can start [6] or prolong outbreaks [7,8]. In institutions where outbreaks occur in ICUs, a common contaminated object in the environment can often be identified as the source. In contrast, in other hospitals, where epidemic infections have become endemic, the clinical and microbiological epidemiology of
these infections often remains obscure. Allen and Green [4] were the first to suggest airborne dissemination of Acinetobacter-carrying particles. Investigating an outbreak of multiply-antibiotic resistant Acinetobacter anitratus in an ICU, a medical ward and three neurosurgical wards, they cultured the outbreak organism from 16 of 82 settle plates. Interestingly, all the positive plates were located within 3m of the colonised patients.

There are studies showing the geographically widespread occurrence of multidrug-resistant A. baumannii strains, which suggested a clonal relatedness of these strains. [9, 10] Three international A. baumannii clones associated with multidrug resistance (European clones I, II, and III) have been reported.

Clonal outbreaks of carbapenem-resistant and OXA-23-producing A. baumannii have been reported in many countries, such as Bulgaria, People’s Republic of China, Brazil, Iraq, Afghanistan, Spain [9,10,11].

2. Aim of the Study

The goal of this study was to promote the phenomenon of disbalance in endemic hospital ECO system which included increase of carbapenemase-resistant Acinetobacter baumannii on account of reduction of MRSA rate in surgical ICU, by long-term monitoring, and the track whether disseminated strains of Acinetobacter were relevant. The final goal of this investigation was to promote specific precautions in order to minimise the acquisition and spread of these emerging infections that are difficult to treat.

3. Methodology

Comparative monitoring from database has indicated that there is a connection among emerging isolation of MDR Acinetobacter baumannii versus declination of MRSA isolates, both originating from surgical ICU patients in a long period of time. 2007/8 has been indicated as a break point period in which there was decrease of MRSA rates (from over 80% to 45%) versus increased rates of Acinetobacter baumanii isolation (from 29% to 40%) [Fig 1].

Acinetobacter baumanii is an important nosocomial pathogen in this Unit. In the period from 1991-1994 the rate of isolation was 29% (N=363). It significantly arised in the period from 2006-2007 to 40% (N=355) and reflect this level in the next 5 years. On the other hand, MRSA became an important isolate in ICU in 1997 with over 80% rates sustaining percentage during the next decade, until 2007 when it was almost twice reduced. [Fig 2].

Amikacin used to be a drug of choice in treatment of Acinetobacter baumanii infections during this long period of time, which has resulted in significant increasing (p=0.0017) the resistance to this antibiotic in the period from 2005-2007 [Fig 3].

That is why carbapenems, firstly imipenem and later on meropenem, were involved in therapy in the early 2000s.

3.1. Design of the Study

Antibiotic resistance among Acinetobacter baumanii has been observed in 3 periods of time: early period 1990 – 2004, middle period 2005-2007 and recent period 2010-2012. Strains of Acinetobacter baumanii originated from
entubated patients in the surgical ICU. They were identified by classical microbiological procedure and confirmed by automatic VITEK technique. Susceptibility patterns to β-lactam antimicrobial drugs were determined by using a standard disk diffusion method according to published standards. Then strains of interest were determined by the agar dilution method, according to established NCCLS and confirmed by automatic VITEK test. Observation included 3 routinely used antibiotics, amikacin, imipenem and meropenem, since the observed strains were MDR.

Student’s t-test of proportion was the epidemiological tool used in order to monitor the changes in resistance to carbapenems, from year to year, in the middle period and in the recent period of observation.

Eight strains of Acinetobacter baumanii were recognized to be resistant to both routinely used carbapenems (imipenem and meropenem) in the recent period, that was not the case with all other strains isolated ever before.

Clonal relatedness of these strains was assessed by pulsed-field gel electrophoresis (PFGE) and multilocus sequence typing in Health Protection Agency London by kindly collaboration with Prof Dr T.Pitt and Dr.Jane Turtone.[1,12]

Presence of the blaOXA-23 gene was screened by PCR using specific primers (OXA-23-A 5′-GGAATTCATGAATAATTTTACTTG-C3′ and OXA-23-B 5′-CGGGATCCGTTAAATAATTCAGTGTC-C3′). Further PCR detection of these clones was performed in Institute of microbiology Skopje.

4. Results

4.1. Acinetobacter Baumanii Ratio in Surgical ICU in the 21 Year Period

The rates of Acinetobacter baumanii isolation in the 21 year period of observation in the surgical ICU, have shown a significant increase in the middle period (2006/7) with 40% (0,0018) rate of isolation. This trend of isolation has been observed in next the “recent period” (38,5%), (2010-2012). [Fig 1].

The rate of isolation of MRSA as predominant pathogen in CARIC with 80% ratio has been found over ten year-period, until 2007/8, when it suddenly decreased to 40% [Fig 2].

4.2. Antibiotic Susceptibility

Comparison of antibiotic resistance to amikacin among the three investigated periods showed a significant ramp from 30% to 80% (p=0.00001) in the middle period (2006/2007) and almost complete (97%) resistance in the “recent period” (2010-2012) among 208 isolates of Acinetobacter. [Tab 1]

The rate of isolation of MRSA as predominant pathogen in CARIC with 80% ratio has been found over ten year-period, until 2007/8, when it suddenly decreased to 40% [Fig 2].

According to Student’s t-test of proportion comparing 2011 and 2010, there was a significant (p = 0,0003) elevation of resistance to imipenem, as well as to meropenem (p=0,00001) (from 33% to 60% to Imipenem, and from 19,5% to 66% for meropenem).

This trend was also observed in the first semester of 2012, but it was still not significant in 2011 for imipenem (p=0,2010) as well as for meropenem (p=0,2598) [Fig 5].

According to the data provided by the supplying service in the Surgery clinic, the use of relevant antibiotics in 2012 versus 2011 displayed 59% increase for meropenem (370amp. vs 180) and 40% decrease for imipenem (1010 amp. vs 2465 amp).

4.3. Molecular Analysis of Resistant Strains

Carbapenem-resistant Acinetobacter baumanii strains (resistant to both carbapenems) were isolated in 2011 by PFEGE analysis, and were similar in dendograms. Five strains had identical dendogram and were designated as UKIMAC1, 2 other similar strains designated as UKIMAC2 and only one unique strain [Tab 2].

Figure 4. Dynamic of the resistance of Acinetobacter spp. to imipenem in the middle period – 2005/2007

Trend of spreading resistance to imipenem reached 73% (p=0.00001) in the “recent period” (2010-12) [Fig 5].

According to Student’s t-test of proportion comparing 2011 and 2010, there was a significant (p = 0,0003) elevation of resistance to imipenem, as well as to meropenem (p=0,00001) (from 33% to 60% to Imipenem, and from 19,5% to 66% for meropenem).

This trend was also observed in the first semester of 2012, but it was still not significant in 2011 for imipenem (p=0,2010) as well as for meropenem (p=0,2598) [Fig 5].

According to the data provided by the supplying service in the Surgery clinic, the use of relevant antibiotics in 2012 versus 2011 displayed 59% increase for meropenem (370amp. vs 180) and 40% decrease for imipenem (1010 amp. vs 2465 amp).

4.3. Molecular Analysis of Resistant Strains

Carbapenem-resistant Acinetobacter baumanii strains (resistant to both carbapenems) were isolated in 2011 by PFEGE analysis, and were similar in dendograms. Five strains had identical dendogram and were designated as UKIMAC1, 2 other similar strains designated as UKIMAC2 and only one unique strain [Tab 2].
5. Discussion

Continuous monitoring is the basic tool in control of HAI, because it provides plenty of data about what happens in hospital ECO system, including appearance of MDR strains among endemic isolates and according to Rampell, changes in balance in hospital ECO system.

By long-term monitoring Acinetobacter baumanii has been confirmed as an important nosocomial pathogen in CARIC in the period 1991-1994, but it was increased in the period of 2007/8 - 2012, on account of MRSA. Similar finding for the same period of time, were referred from the investigation in some other countries such as Brazil or Taiwan [17,18].

The comparative study indicated significant changes in EKO system in 2007/8 in investigated ICU. MRSA rates were almost double reduced and on the other side, rates of Acinetobacter baumanii significantly increased. [13]

Considering many differences in epidemiological characteristics of these two microorganisms, it was assumed that global or local conditions in the unit have been changed and/ it can be connect with the global changes in the climate [19,20]. Therefore Acinetobacter isolates became an important problem in this Unit, especially when carbapenem resistance was noticed in 2011 among eight strains which had been nonsusceptible to all other antibiotics tested by the agar dilution method.

All isolates of Acinetobacter were nonsusceptible to all of the antibiotics tested by the agar dilution method except amikacin until 2007 when resistance achieved 80%. After that imipenem was involved as alternative antibiotic therapy. In the next 5 years resistance among acinetobacters was spread very fast, almost completely to aminoglikozide (93%) and very high to imipenem (73%). Since therapeutic choice of Acinetobacter infections was small, meropenem was involved uncontrolled in therapeutic routine practice [Tab3].

6. Conclusion

Carbapenem resistant Acinetobacter baumanii (European) clone II, became significant pathogen in CARIC, replacing MRSA which was predominant cause of infections in over ten years period of time. This MDR clone expressed big capacity for intra/inter-hospital dissemination of the clone, which was confirmed by literature data and was due to un rational antibiotic usage in CARIC.

The new situation in this hospital ECO system indicated revision of hospital control strategies and applying new specific precautions. It was recommended: strong artificial control of air humidity, negative pressure in the critical room, proper care for bed-linen, replacement cotton with synthetic pillow, proper laundry of bed-linen, removal of mattress (once being Acineto-positive). Strong monitoring should be conduct over effect of recommended precautions for the following period of time.

References

This led to sudden development of meropenem-resistance. Among eight carbapenem resistant Acinetobacter baumanii tested representatives three distinct strains were detected by PFGE. Five of them could possible belong to the same source – type UKIM01AC-1 and another two were connected - UKIM01AC 2. All representatives of UKIM01AC-1 were PCR positive for bla (OXA-23-like), in addition to the bla (OXA- 51-like) gene, which was intrinsic in Acinetobacter baumanii. All isolated strains belonged to European clone II lineage. [14], although there are data for A.baumanii isolates positive for bla (OXA-23-like) on american continent [17]. This clone dispersed very fast in 2012 and achieved the rate of 61,9% (N=84).
