Abstract: *Culex pipiens* is the common mosquito in Egypt and worldwide species. There is limited evidence on the effects of breeding place nature on the susceptibility of *Cx. pipiens* to different insecticides. This study aims to evaluate the effects of some physiochemical parameters of different breeding sites in Egypt on *Cx. pipiens* susceptibility to some recommended insecticides. Mosquito larvae were collected from fresh and sewage water from the selected sites at different areas in Egypt. Water was analyzed in the laboratory to determine salinity and pH. Bioassays and biochemical assays were carried out to determine susceptibility of both larvae and adult under different physiochemical parameters. Larvae and adult that were collected from sewage water with high salinity and acidic medium showed higher resistant to all tested insecticides than those of fresh water with low salinity. The present study provided information of the susceptibility of *Cx. pipiens* mosquito larvae and adult to some insecticides commonly used under different environmental changes.

Keywords: *Culex pipiens*, Insecticide Resistance Assays, Breeding Places, Salinity, pH

1. Introduction

In Egypt, the mosquito *Culex pipiens* is the principal mosquito vector of filariasis and some arboviruses such as West Nile Virus and Rift Valley Fever virus [1, 2]. *Cx. pipiens*, therefore, is the main target in control programs against these diseases.

Culex pipiens larvae invest all kinds of aquatic habitats for breeding, in which, their physiochemical parameters are important factors for survival and development of mosquitoes. The breeding sites of mosquitoes are sometimes contaminated with pollutants from various sources such as sewage from industrial and agricultural fields [3, 4].

Physiochemical parameters such as temperature, salinity, and pH have a significant influence on the occurrence and larval abundance among mosquito species [5]. Also, these

characteristics may have some effects on mosquito vectors susceptibility to traditional used insecticides. Understanding of breeding behavioral pattern among mosquito populations is one of the key elements for reaching the goal of mosquito control.

There is limited evidence on the effects of breeding site nature on the susceptibility of mosquitoes. In this study, the effect of physiochemical parameters at different breeding sites on susceptibility of *Cx. pipiens* to different insecticides was studied. The larvae were collected from different breeding places in selected localities represent different Egyptian governorates (Aswan, Kafr El Sheikh and Suez).

2. Materials and Methods

2.1. Study Area

Culex pipiens larvae were collected from Aswan, (Upper Egypt), Kafr El Sheikh, (Nile Delta) and Suez governorates. From each governorate larvae were collected from both sewage and fresh water. Breeding site water samples were collected to measure the following physiochemical parameters; the salinity, pH as well as temperature. Measurement of these parameters was carried out using water test (Hanna instrument HI991301).

2.2. Collection of *Culex pipiens* Larvae

As soon as the localities were determined and during regular mosquito surveillance sampling, sufficient dips with a 7 cm diameter metal ring, to which mouslin net was fixed, with about 1.3 meters long wooden handle. Collection of *Cx. pipiens* larvae was conducted by dropping the net gently and smoothly under the water surface of the selected area. Representative sample of the population was transferred to 20 cm diameter enamel plates, then were exposed to sun – light. The larvae were transferred to the laboratory in jars that filled with the water from their habitat. The larvae were identified morphologically to the species level [6].

Sufficient numbers of larvae were used for larval bioassay and biochemical assays. Other larvae were reared in laboratory until emergence of adult. They were hold in the insectary in which temperature was maintained at 25 ± 3 °C and humidity between 70- 80%. The emerging adults were fed on 10% sucrose solution until four days then used for adult bioassay in addition to biochemical assays [7].

2.3. Toxicological Studies

2.3.1. Larval Bioassay

In this study, three organophosphorus insecticides; temephos, chlorpyrifos and primiphos methyl recommended for mosquito larval control by the World Health Organization's Pesticide Evaluation Scheme (WHOPES) for evaluation of mosquito larvae resistance were used [8].

Single-concentration diagnostic tests were conducted to monitor insecticide resistance [9]. The diagnostic concentrations for tested insecticides were; 0.02 ppm temephos, and 0.01 ppm chlorpyrifos, while the diagnostic concentration of primiphos methyl was calculated by measuring LC_{99} of susceptible population and then duplicated (0.1 ppm).

The bioassay was conducted according to WHO standard procedure [10] with four replicates for each test. Twenty five Larvae per replicates were added in beaker contained 249 ml tap water and 1 ml of the insecticide concentration was infiltrated under the water surface with a pipette. Other four replicates were treated with 1 ml ethanol as control.

2.3.2. Adult Bioassay

Three pyrethroid insecticides (Lambda- cyhalothrin, Deltamethrin and Permethrin) commonly recommended for mosquito adults control were tested against the six studied *Cx. pipiens* populations. The proposed diagnostic

concentration by WHO [9, 11] for each insecticide was used to monitor insecticide resistance (0.05% Lambda-cyhalothrin, 0.05% Deltamethrin and 0.75% Permethrin).

The adult bioassays were performed using WHO test kits and method for measuring insecticide susceptibility [11]. Each experiment consisted of three replicates with twenty females in each. Non-blood fed, 3 to 5 days old females were exposed to insecticide-treated filter papers. The mosquitoes were exposed to the insecticide for an hour with the assay cylinders in a vertical position. After the exposure, mosquitoes were transferred into the holding tubes with untreated papers and allowed a 24 hour recovery period after which mortality was recorded. A group of 20 mosquitoes were exposed to papers treated only with the used solvents (ethanol) for an hour as control. The bioassay was carried out at 25 ± 2 °C and the mosquitoes were supplied with a 10% sugar solution meal during the recovery period.

2.4. Biochemical Assay

2.4.1. Preparation of Mosquito Extracts

For total protein, acetylcholinesterase and glutathione-S-transferase assays, 50 mg samples of mosquitoes were mechanically homogenized in 1 ml distilled water by a chilled glass telfon homogenizer. Homogenates were centrifuged at 8000 r.p.m. for 15 min at 5°C in a cooling centrifuge and the supernatant were kept in a deep freezer till used [12].

2.4.2. Determination of Total Protein Activity

Protein concentrations were determined by incubating 10 µL of larval homogenate with 290 µL of Bio-Rad protein assay solution for 10 min. Absorption was then measured at 570 nm and bovine serum albumin was used as the standard using double beam ultraviolet / visible spectrophotometer (spectronic 1201, Milton Roy Co., USA) [13].

2.4.3. Determination of Acetylcholinesterase Activity

Acetylcholinesterase (AChE) activity was measured using acetylcholine bromide (AChBr) as substrate; the resulted colour was measured colorimetrically at 515 nm [14].

2.4.4. Determination of Glutathione-S-transferase Activity

The activity of GST was evaluated using three-ml reaction mixture contained (0.05 ml of 50 mM CDNB [1-chloro-2, 4-dinitrobenzene], 0.15 ml of reduced glutathione (GSH) were added to 2.79 ml of 40 mM buffer saline (pH 6.8) and 0.01 ml enzyme source) was added. The mixture was incubated for 2-3 min at 20°C. The increasing in absorbance value (OD) was recorded for 5 min, and the GST activity ($\mu\text{M mg protein}^{-1} \text{ min}^{-1}$) was then calculated [15].

2.5. Data Analysis

One-way analysis of variance (ANOVA) was used to compare insecticide resistance profiles in different breeding sites. All levels of statistical significance were determined at $P < 0.05$. Statistical analyses were carried out using SPSS version 20 (2012) [16] for Windows (SPSS Inc, USA). Biochemical assay results were calculated and plotted using Microsoft Excel (Microsoft Corporation, 2010).

3. Result

3.1. Insecticide Susceptibility of *Culex. pipiens* Populations

In figure 1; the susceptibility of the *Cx. pipiens* larvae to the three tested insecticides is plotted against the different measured characteristics of breeding water (salinity, pH and temperature). On other hand, figure 2 showed the effect of these parameters on the susceptibility of the emerged adults to the test adulticides.

Data in figures (1 and 2) showed that, sewage water with high salinity and acidic medium ranging from (2.5- 3) and (6- 6.4), respectively decreased susceptibility of *Cx. pipiens* larvae to all tested insecticides, while fresh water with low salinity and alkaline medium ranging from (0.3- 0.64) and (7.6- 8.6), respectively resulted more sensitive mosquito larvae to all tested insecticides.

Also, results showed that *Cx. pipiens* mosquito larvae collected from Kafr El Sheikh were more resistant to all tested insecticides followed by Suez ones, while Aswan mosquito larvae were the most susceptible population examined. On other hand, temephos was the most effective larvicides, while lambda- cyhalothrin was the most effective adulticides.

The collected larvae from sewage water in Kafr El Sheikh showed significant decrease in susceptibility ($p < 0.05$) to all larvicides with mortality rates (40, 60 and 85% to chlorpyrifos, primiphos methyl and temephos, respectively) if compared with those of fresh water larvae (60, 90 and 100% mortality for chlorpyrifos, primiphos methyl and temephos, respectively) (Figure 1). Also there was significantly decrease in susceptibility of emerged adult ($p < 0.05$) from sewage water with mortality rates (67, 70 and 75% to permethrin, deltamethrin and lambda- cyhalothrin, respectively), while the fresh water larvae reduced mortality rates in emerged adults (73, 78 and 82% to permethrin, deltamethrin and lambda- cyhalothrin, respectively) (Figure 2).

Larvae that were collected from sewage water in Suez, showed significant decrease in susceptibility ($p < 0.05$) after exposure to primiphos methyl and chlorpyrifos as larvicides (82, 45%, respectively) if compared with percent mortality (100, 70%, respectively) in fresh water. The emerged adults had the same manner against permethrin as adulticide (72%) if compared with the effect of characteristics of the fresh water (80%). However, there was no significantly difference in susceptibility ($p > 0.05$) between sewage water and fresh water after exposure to temephos as larvicide (90, 80%, respectively). As well as deltamethrin (75 and 84%, respectively) and lambda- cyhalothrin (81, 87.5, respectively) used as adulticides (Figures 1, 2).

In Aswan, there were no significantly differences in insecticide susceptibility of sewage mosquitoes and fresh water ones ($p > 0.05$), except in the treatment with chlorpyrifos and primiphos methyl as larvicides as well as permethrin as adulticides ($p < 0.05$).

Culex pipiens population collected from both sewage and fresh breeding sites showed high mortality percent (100%) after exposure to temephos, while primiphos methyl showed mortality percent (87, 100%) in sewage water population and

fresh water one, respectively. Chlorpyrifos recorded decrease in susceptibility of sewage water population with mortality 61%, while, fresh water with mortality 94% (Figure 1).

As adulticides permethrin showing some degree of resistant in sewage water population 76%, while, 87% mortality indicated in fresh water one. Deltamethrin recorded mortality percent 83% in sewage water and 87% in fresh water populations. Lambda- cyhalothrin was most effective insecticides with mortality percent 84% in sewage water and 90% in fresh water populations (Figure 2).

Figure 1. Physiochemical parameters of breeding water and their effect on susceptibility of *Culex pipiens* larvae to different insecticides.

Figure 2. Physiochemical parameters of breeding water and their effect on susceptibility of emerged *Culex pipiens* adults to different insecticides.

3.2. Biochemical Assay

In order to explain the response of *Cx. pipiens* that brought from different breeding at different localities the biochemical assay was carried out.

After measurement of the total protein in all tested mosquitoes, the values were used to calibrate the activity of acetylcholinesterase and glutathione- S- transferase enzymes.

From figures 3, 4, 5 and 6, AChE and GST activities exhibited higher levels in sewage mosquitoes than fresh water ones.

In Kafr El- Sheikh originated populations AChE level recorded elevation in both larvae and adult from sewage population (3.3 and 7.9 $\mu\text{g AChBr/min/mg protein}$,

respectively). On other hand, the activity of AChE decreased in both larvae and adult collected from fresh water (2.04 and 6.2 for AChE $\mu\text{g AChBr/min/mg protein}$, respectively). In the same manner GST showed elevation in both larvae and adult (2111 and 2813 n mole sub conjugated/min/mg protein, respectively), and decreased in both larvae and adult collected from fresh water bodies (2079 and 1409 n mole sub conjugated/min/mg protein, respectively).

In Suez populations, AChE level recorded elevation in both larvae and adult collected from sewage population (2.6 and 6 $\mu\text{g AChBr/min/mg protein}$ for AChE, respectively). On other hand, the activity of AChE decreased in both larvae and adult collected from fresh water (1.3 and 4.2 $\mu\text{g AChBr/min/mg protein}$, respectively). In the same manner GST showed elevation in both larvae and adult (3922 and 2303 n mole sub conjugated/min/mg protein, respectively) and (2010 and 1013 n mole sub conjugated/min/mg protein for GST, respectively).

In Aswan, populations AChE level recorded elevation in both larvae and adult collected from sewage population (2.2 and 5.43 $\mu\text{g AChBr/min/mg protein}$, respectively). On other hand, the activity of AChE decreased in both larvae and adult collected from fresh water bodies (1.5 and 3.8 $\mu\text{g AChBr/min/mg protein}$, respectively). In the same manner GST showed elevation both larvae and adult (1107 and 1627 n mole sub conjugated/min/mg protein, respectively) and (895 and 998 n mole sub conjugated/min/mg protein, respectively).

4. Discussion

The mosquito control continues to be an important strategy in controlling and preventing the mosquito-borne diseases. The primary approach used for mosquito control is mainly relied on pesticides. However, very few pesticide types are currently registered for mosquito control. Furthermore, many mosquito species have developed resistance to various classes of pesticides [8, 17]. Insecticide resistance has been known to be prevalent in several insect species including mosquitoes. It has become a major problem in vector control programme due to pesticide resistance through detoxification enzymes. Current environmental trends including climate change, increased exchanges and urbanization, affect the distribution of disease vectors and subsequently the transmission and incidence of human pathogens [18].

The rapid change in environment and rise developing industrial waste increase the pollution on mosquito breeding places and affect the chemical use in control mosquitoes.

The present study provided information of the susceptibility of *Cx. pipiens* mosquito larvae and adult to some insecticides commonly used under different environmental changes. The study investigated the effect of physiochemical characteristics changing due to variation of the breeding places; sewage and fresh water on the insecticide susceptibility of three mosquito populations

from different three Egyptian governorates; Kafir El Sheikh, Suez and Aswan. Physiochemical parameters (salinity, pH and temperature) appeared to significantly influence the larval insecticide susceptibility as well as subsequent emerging adult. The study revealed an evidence of the effect of the nature of breeding sites on susceptibility of mosquito.

The present study indicated that, susceptibility of swage *Cx. pipiens* larvae and adult populations was significantly lower (high salinity and low pH value) than fresh water populations in all three tested governorates.

Physiochemical feature in mosquito breeding sites has some influence on mosquito vector oviposition, survival and spatial distribution [19]. The size of the adults of *Aedes* mosquito emerged from sewage drains was bigger than those emerged from rest of the larval habitats [20]. These variations may be due to that the resource content of the sewage drains was higher than other habitats, which contributed to the development of large mosquitoes with higher nutrient reserves [21, 22].

In general, the present study revealed that, temephos was the most effective larvicide against all populations collected from different environmental conditions, with high percent mortality 100% followed by primiphos methyl, then chloropyrifos. Moreover, lambda- cyhalothrin was the most effective adulticide against all adult populations developed from larvae collected from different environment followed by deltamethrin and the lowest effective one was permethrin. On other hand, *Cx. pipiens* that were collected from Kafir El Sheikh showed the higher resistance to the most of tested insecticides, this may be due to extensive use of chemical insecticides.

To explain change in the response of mosquitoes to the used insecticides with difference in breeding habitats, a biochemical assay was conducted for two enzymes which are known to be implicated in insect resistance. The enzymes are acetylcholinesterase (AChE) and glutathione- S- transferase (GST). AChE is a common resistance mechanism observed in several species of arthropods [23]. Numerous studies have demonstrated that the increased metabolic detoxifications were involved in organophosphate resistance in many insect pests [24].

The results of biochemical analysis revealed elevation in the activity of both enzymes. The observed high levels of AChE and GST is supported the increase insecticide resistance in field populations of sewage water.

The present results agree with [25] who estimated that, number of organisms are known that tolerate acidic or alkaline conditions, but mosquitoes appear to be the most proficient pH regulators yet described. *Aedes aegypti* was unusual in their ability to survive and developed in waters ranging from pH 4 to 11. Also mosquitoes bred under different conditions showed considerable changes in mortality rates and body weight, with nutrition being the major factor, they also demonstrated that temperature, crowding and availability of nutrition during the larval stages directly or indirectly modulate 24 hours mortality in the adult

when exposed to permethrin [26].

Salinity had a small but significant negative impact on the toxicity of *Bacillus thuringiensis* toxin to *Aedes aegypti* larvae. This had implications for the use of *B. thuringiensis* toxin as a larvicide in brackish waters [27, 28].

As mentioned, it has been shown before that any change during the larval stage life span influence the insecticide susceptibility of the adult mosquito [29].

5. Conclusion

It could be concluded that, the variation of the properties of breeding site characteristics had great effect on the susceptibility of *Cx. pipiens* to different insecticides. The findings from this study strengthen the importance of environmental contributions and changes to the expression of resistance to insecticides in *Cx pipiens* mosquitoes. So we need to give environmental factors more attention especially in insecticide resistance assay manuals.
