Special Issue: Environmental Social Impact Assessment (ESIA) and Risk Assessment of Crude Oil and Gas Pipelines.

Vol. 3, No. 6-1, 2015, pp. 56-65. doi: 10.11648/j.ijema.s.2015030601.17

Abstract: This paper introduces an oil spill scenes from a crude oil pipeline. The oil spill is presented in a short narrative, however a series of pictures taken from the accident sites were included in the paper. The pictures are in the time order of events during the accident. The ferocity of the events can be seen and followed through pictures. The paper creates and provides the sense and understanding of oil spills to the researcher working in this field.

Keywords: Oils Spills from Crude Oil Pipelines Rupture of a Crude Oil Pipeline, Cleaning Oil on the Shorelines, Use of Oil Booms, Oil Debris Storage, Fishnetted Boom, Usage of Booms

1. Introduction

There are abundance of papers on oil spills; discussing oil spill transport modelling, risk analyses, ESIA (Environmental and Social Impact Assessment), behavior of oil land and in marine areas, and other related problems of oil spills, [1 – 10]. In this paper, an actual oil spill from a crude oil pipeline is introduced and presented through photographs. A spill accident was happened by ruptured the 18-inch crude oil pipeline. An oil spill of almost 40 000 barrels gushed into a dam lake in a land locked area. The spill was very unusual oil spill since, it was not a land spill or a marine spill or a lake spill. It was spill of dam lake spill and very crucial; since the water is being use for irrigation and domestic purposes.

The accident was happened by rupturing 18-inch crude oil pipeline, which previously was removed from the lake area to prevent accidents. The rupturing was happened during earthwork activities, most likely there was a hit from a backhoe, Figures 1-2. Then, oil flowed through an irrigation channel from the ruptured pipeline to the lake. The pipeline administration was not prepared such an event and there were not appropriate equipments in the area. The cleaning crews tried to recover oil by equipments that they could acquire from the local sources. The modern equipment arrived in the area within a week, and modern recovery was initiated and completed.

The area was very fragile and shorelines were cleaned up by hand labor and the collected debris was stored local and

outside storage areas. At the end 25 000 barrels of oil was collected; the rest is recovered and taken from water and shorelines.

Figure 1. Ruptured pipeline, [11] and [12].

Figure 2. Another view of ruptured pipeline, [11] and [12].

Some light volatiles dissolved in water might end up downstream, however the dam lake is a very large water body; and the influence on the agriculture was extremely minimum.

A fishnetted booms were prepared and used to recover the oil from the water, [11]. Under these circumstances, every possibility and capacity was used to protect the environment. The pictures are from an archive, [12].

2. Analysis of the Response

2.1. Source of the Oil Spill

The oil spill started from a ruptures pipeline during earth works in the area. The spilled oil found its way to the dam lake through an irrigation channel used for adjacent agricultural areas. Unfortunately, the shutting down the valves were delayed around six or seven hours, Figures 3 - 8. The channel was located, closed and boomed to prevent further flow of oil from the ruptured pipeline. The pipeline is repaired for oil transportation from the oil field. The accident was happened in a remote area, a trailer was furnished as a command room for IC (Incident Command) operations, Figures 9 – 10. The movements of oil was observed bu using three percent law of oil spill movements on water; and the wind vector was obtained from local authorities and/or guessed by looking at local conditions for deployment of manpower and equipment. There was no computer realated help at beginning.

Figure 9. Command room for response, [11] and [12].

2.2. Cleaning Operations

The oil spread to various areas was located; and necessary actions were taken to recover and prevent oil further spreading, Figures 11-14.

The coves on the shore areas were immediately boomed to prevent spreading oil from these secluded areas. The skimmers were employed to get oil out of water, Figure 15.

Figure 15. Working skimmer on the oily shoreline, [11] and [12].

Figure 16. Hand cleaning the shoreline, [11] and [12].

Some areas were very difficult and the only choice was hand cleaning, Figure 16 - 17. The organizing and managing the hand cleaning operation was quite complicated and expensive. This method can only be viable if there is no other choice.

The situation was constantly monitored and discussed, in the command room and field, Figure 18. The decisions in field were quite effective, since they were made through and during combat situations.

Figure 17. Collecting debris, [11] and [12].

Figure 18. Lunch break and discussions, [11] and [12].

A fishnetted booms were prepared and used to recover oil from water surface. They were used to collect oil on the water; and also in the water column, Figures 19 – 22. They were very useful when the modern skimmers were not on the scene.

The oil was still in the environment, Figure 23 and hand cleaning that was a very expensive operation was going on. A hand recovery is presented by Figure 24. Modern and new equipments including a boat skimmer arrived in the accident area; and they were started to use for recovery, Figure 25 - 26.

Figure 25. A local recovery boat, [11] and [12].

Figure 26. New and modern equipments were in the area, [11] and [12].

The oil collecting materials and debris are presented by Figures 27- 30. The equipment and materials must be repaired; and cleaned for reusing and recycling, Figures 31 -32.

Some of the oil spill response equipments are shown by Figures 33 – 36.

Figure 27. Oily booms, [11] and [12].

Figure 28. Oiled stones on the shore, [11] and [12].

Figure 30. Collected oil, [11] and [12].

Figure 31. Preparing booms for reuse, [11] and [12].

Figure 32. Drying the used booms, [11] and [12].

The equipments are in quite stress, they must be well maintained, repaired and constantly cleaned. There are many different type equipments and they require special expertise and this expertise must be present in the accident area.

The aim is preventing any further contamination in the area during cleaning and recovery activities. The bags, linings and barrels were used with a great care and attention to prevent any damage in the environment.

Figure 33. Washing an equipment, [11] and [12].

Figure 34. Skimmer on the shore, [11] and [12].

Figure 35. Loading debris, [11] and [12].

Figure 36. Loading portable storage, [11] and [12].

The collected debris was buried in the lined local and nonlocal pits, Figure 37-46. Debris from which oil can be recoverable was transported to organizations that could treat this material. The oil directly recovered from the spill was sent to a refinery that could process this kind weathered oil.

The debris fields were carefully organized to prevent any further damage to the environment, specially groundwater, surface water and land resources.

Figure 37. Hardened oil, [11] and [12].

Figure 44. Debris field and barrels, [11] and [12].

Figure 45. Another view debris storage, [11] and [12].

Figure 46. Barrels loaded by debris, [11] and [12].

The selected debris storage area must not interact with any environmental concerns; these are air, water, land and living habitats. In addition, the lining of the debris area must be designed that can take all environmental stresses. The debris area must be organized properly for using in the designated area properly, Figures 47 – 50. The post cleaning operations will continue even after careful cleaning operations performed in the area, Figures 51 – 52.

Figure 50. Another view for organizing debris, [11] and [12].

Figure 51. Cleaning stones on the shoreline, [11] and [12].

Figure 52. Another view cleaning stones, [11] and [12].

The accident area should be inspected for further cleaning even after cleaning the area. In these situations, there are always uncleared areas, Figures 53 – 58. These areas must be cleaned further. It is of course, some small oil leftovers will be left to time.

Some bacterial effects and environmental condition will erode leftover hydrocarbons in the area; however some remedies may stay in the region for a long time.

3. Conclusion

The paper is aimed at better understanding of oil spills by presenting photographically real time situations of an oil spill accident; and provides experience to planner and responders. It is almost certain that no spill will be look like and similar to any other previous oil spills, however this paper may and will improve decision making abilities of IC (Incident Command) personnel during actual oil spills. In other words the paper will provide significant experience and feeling to oil spill responders about combat situations.
