Abstract: Small scale screw extrusion machine is designed and tested for making compact sawdust briquettes in rural area in Indonesia. The extrusion machine is powered by 5,5 HP gasoline internal combustion engine. In this work, briquetting machine is used to produce sawdust briquettes which two different ratios of starch-sawdust. The ratios of starch to sawdust are 1:4 and 2:4. Sawdust briquettes have a length of 3 cm and 4 cm for both composition ratios. The performance of the machine is investigated in term of density changes of briquettes after three days. The density of sawdust briquettes just after extrusion process is compared with the density of sawdust briquettes after 3 days sunlight drying. The result shows that the extrusion machine is able to produce compact sawdust briquettes with different ratios of starch to sawdust. The result also indicates that 3 cm long sawdust briquettes which starch to sawdust ratio 2 : 4 has the lowest density changes and has the highest compressive strength.

Keywords: Briquettes, Sawdust, Extrusion, Density

1. Introduction

The demand of fuel wood is still high, mainly for cooking purpose in rural area in Indonesia. The demand of biomass energy in rural area in Indonesia is about equivalent with 225 million barrel crude oil [1].

Figure 1. Demand of biomass fuel in Indonesia

Many efforts have been made for supplying the demands, including development of biomass briquettes technology. Briquetting of biomass has been found as a viable technology

for upgrading biomass materials, including agricultural residues, particularly in developing countries which abundant biomass waste resources [2]. Various biomass wastes have been utilized for biomass briquettes. Many works on development of biomass briquettes have been done from various types of biomass wastes, such as rice husk [3], and paper pulp [4].

Characteristic of biomass briquettes is affected by many factors, such as briquette's size, moisture content and compacting pressure. Compacting pressure affects the size and shape of biomass briquettes [2]. There is a maximum die pressure for given die size and storage condition beyond which no significant bonding effect can be achieved. Mechanical properties of biomass briquettes can be increased with addition of different type of biomass [4]. Addition of sawdust and paper mill in the mixture can improve compressive strength of biomass briquettes.

Biomass briquettes can be utilized as feed stock of gasifier. Singh *et al.* [5] produced different length coconut shells briquettes with modification pressing machine. The briquettes have a length of 90, 60, and 35 mm. The 35 mm briquette is the best characteristic for feedstock of gasifier.

Indonesia has biomass energy potential approximately 46 GW, but only 0,3 GW has been utilized, including sawdust

biomass from wood processing home industry. Sawdust has been used for making biomass briquettes by pressing machine. The machine generally has high production capacity and needs trained worker. These limit the application of the pressing machine technology in rural area. In this research, small scale extrusion machine is fabricated and tested to produce biomass briquettes from mixture of starch and sawdust. The extrusion machine is designed with small gasoline internal combustion engine which easy to operate. The extrusion briquetting machine is proposed for rural area which abundant source of sawdust in Indonesia.

ENERGI NON FOSIL	SUMBER DAYA	SETARA	KAPASITAS TERPASANG
Tenaga Air	845.00 juta BOE	75.67 GW	4.2 GW
Panas Bumi	219 Juta BOE	27.00 GW	0.8 GW
Mini/Micro Hydro	0.45 GW	0.45 GW	0.206 GW
Biomass	49.81 GW	49.81 GW	0.3 GW
Tenaga Surya	-	4.80 kWh/m ² /hari	0.01 GW
Tenaga Angin	9.29 GW	9.29 GW	0.0006 GW
Uranium (Nuklir)	24.112 ton* e.g. 3 GW untuk 11 tahun

2. Experimental Work

In this work, small screw extrusion machine is designed and manufactured prior to sawdust briquetting process. The main components of extrusion machine are 5,5 HP gasoline internal combustion engine, screw extruder, gear box, transmission system, and machine frame. Figure 3 and Figure 4 show the screw and the die of the extrusion briquetting machine.

Figure 5. Small scale briquetting machine.

Briquettes are produced from a mixture of sawdust and starch as a bonding material. The mixtures have two different ratios of starch to sawdust, 1 : 4 and 2 : 4. The sawdust briquettes are produced in 3 cm length and 4 cm length for each composition ratio.

In this work, the density of briquettes for each length and composition is investigated before drying and after 3 days drying. The result is then compared to obtained density change after 3 days drying. The compressive strength of briquettes is also tested after 3 days sunlight drying. The measurement of compressive strength is conducted in Laboratory of Material Technology, IST. AKPRIND Yogyakarta.

Figure 6. Starch and sawdust.

Density of briquettes is obtained by measuring the weight and volume of briquettes, and can be expressed as

$$\rho_b = \frac{m_b}{V_b} \quad (1)$$

where m_b is a weight of briquette and V_b is a volume of briquette.

Meanwhile, percentage of density change is calculated with

$$\Delta\rho = \frac{\rho_{b,wet} - \rho_{b,dry}}{\rho_{b,dry}} \times 100\% \quad (2)$$

where $\rho_{b,wet}$ is density after drying and $\rho_{b,dry}$ is density of briquette after 3 days sunlight drying.

(b) length of 4 cm

Figure 7. Sawdust briquettes.

3. Results and Discussions

Figure 8 and Figure 9 show an average density of sawdust briquettes before drying and after 3 days sunlight drying. Sawdust briquettes which 1 : 4 composition ratio of starch to sawdust has higher average density than briquettes which composition ratio of 2 : 4 for both briquette length. This is because more sawdust composition in briquettes of 1 : 4 ratio. Briquettes which composition ratio 1 : 4 and length of 4 cm has the highest density in order of magnitude 2.118 gr/cm^3 . In contrast, briquette which composition ratio 2 : 4 and length of 3 cm has the lowest density in order of magnitude 0.864 gr/cm^3 .

Average density just after extrusion

Figure 8. Average density just after extrusion

Figure 9. Average density after 3 days drying

After 3 days drying, briquettes which ratio 1 : 4 and length of 3 cm has the highest density about 0.524 gr/cm^3 . Meanwhile, the lowest density is 0.439 gr/cm^3 for briquettes which composition ratio 1 : 4 and length of 4 cm.

Reduction in density of briquettes after 3 days drying is shown in Figure 10. Briquettes which mixture ratio 2 : 4 and 3 cm length experience the lowest density reduction, in contrast with briquettes which mixture ratio 1 : 4 and 4 cm length.

Figure 10. Density change after 3 days drying

Figure 11 shows an average compressive strength of briquettes for both mixture composition ratios. Briquettes which composition ratio of 2 : 4 and length of 3 cm has the highest compressive strength in order of 0.088 kg/mm^2 .

Figure 11. Briquette's compressive strength.

4. Conclusions

It can be concluded that the screw extrusion machine is easily operated for producing sawdust briquettes. The briquettes which composition ratio 2 : 4 of starch to sawdust and length of 3 cm has optimum mechanical properties in term of density change and compressive strength. The minimum density change is 16. 08% and maximum compressive strength is 0.088 kg/mm².
