Abstract: Single pane glazed flat solar heaters found rather wide application for domestic hot water supply. However, the practice of use shows some discrepancy between estimated and observed data: in one case the temperature of hot water does not conform to the expected pattern, in other case doubts arise about correctness of their sizes, in some cases the quantity of heated water is not enough, etc. Because of such divergence of opinions, it is becoming necessary to think about correctness of existing methods of sizing and designing of flat plate solar water heaters. This article attempts to develop a new structure and improved method for calculation and design of flat plate solar water heaters. Analysis proved relatively higher energy and cost effectiveness of the new structure of flat plate solar water heater.

Keywords: Flat, Solar, Heater, Tunnel, Similarity, Criterion, Nusselt, Prandtl

1. Introduction

The algorithm of performance of flat plate solar water heater consists of following steps

- (1) Evaluation of optical losses and penetration rate of solar radiation through glazed cover.
- (2) Absorption of penetrated solar radiation by absorber sheet and rising the flat plate absorber's and consequently the hot tunnel and hotbox air temperatures. Nevertheless, as indicates H. P. Garg [1], usually the absorber plate temperature is unknown and is difficult to calculate or measure because it is a function of several parameters. To solve this problem the authors of this paper used a new approach allowing determining mentioned temperatures.
- (3) Transferring of hot tunnel's air heat to the water, flowing in the water metallic meander tube, laid in the hot tunnel.
- (4) Storing of hot water in a tank and consume it, when there is need.

Described mechanism impels to use the mane principals of heat transfer and solar irradiant to developing a new, more energy efficient structure and method for calculation and design of suggested flat plate solar water heater.

2. New Structure and Operation of a Flat Plate Solar Water Heater

Fig. 1 displays the suggested structure of a flat plate solar water heater.

Figure 1. New structure of flat plate solar water heater.

1- aluminum frame, 2- thermal insulation layer, 3- copper or aluminum absorber sheet, 4- tap water inlet tube, 5- hot water outlet tube, 6- 180° bend water meander tube, 7- glass cover

The new structure of flat plate solar water heater consists of powder coated aluminum frame (hotbox) (1) the bottom and sidewalls of which are covered by mineral wool thermal insulation layer (2). For absorbing solar rays and converting

them into heat on the insulation layer (2) a copper or aluminum absorber sheet (3) and glass cover (7) are installed. On the absorber sheet a narrow air tunnel with length about $l=1$ m and height $h_{tun.}=0.05$ m is created. In the tunnel a copper, 180° bend water meander tube (6) with, exterior diameter $d_{ext.}=0.024$ m is laid. Through the inlet of tube (4) enters tap water and hot water exits through the outlet tube (5). Water meander tube and interior surface of the water heater are covered with dark color. The inside surface and inside air absorb penetrated solar energy $Q_{sol.in}$ and are heated up to an appropriate conditional temperature $t_{cond.}$, °C. Then the solar energy $Q_{sol.in}$ transfers to the water, flowing in water 180° bend meander tube and heats it up to a final temperature $t_{w.fin.}$. The required quantity and temperature of hot water are provided by the heliosystem consisted of solar plate water heater units, arranged parallel and in series.

3. Accounting of Simultaneous Impact of Solar Radiation and Ambient Temperature on Functionality of Flat Plate Solar Water Heater

All types of solar water heaters simultaneously are sensitive to intensity of solar irradiance I , W/m^2 and temperature of ambience (outside air t_{out}). For this reason, in cold climatic conditions, the ambient temperature t_{out} and as well the inside temperature of the hot tunnel, at nighttime and in the early morning are the same and negative. Therefore, for correct determination of absorbed solar heat $Q_{sol.in}$ and radiation conditional temperature t_{cond} in tunnels, should be analyzed the daily unstable changes of solar irradiance I , W/m^2 , and temperature of ambience (outside air t_{out}), which take place simultaneously. Daily changes of outside temperature of given area are shown by the following cosine harmonic function [2]:

$$t_{out} = t_{0.out} + A_t \cos \frac{2\pi}{T} (Z_t - Z_{t.max}), \quad (1)$$

Figure 2. Wintertime change of outside design temperature in the course of a day for Yerevan city:

Curve 1-daily course of outside air variable temperature;
Curve 2-daily average temperature of outside air.

where:

t_{out} - running outside temperature during a day, °C,

A_t - amplitude of daily temperature change (temperature fluctuation range),

$T=24$ hour - daily period of oscillation of the outside temperature,

Z_t - instant time of a day when given temperature occurs,

$Z_{t.max.}$ - instant time of the day, when outside air temperature reaches to its highest value.

The diagram of Fig. 2 represents the course of daily change of wintertime outside temperature in Yerevan city [2].

Based on guide of construction climatology of Armenia [2] the wintertime daily course of irradiance changes for Yerevan city represents the Fig. 3.

Figure 3. Wintertime course of changes of irradiance I , W/m^2 for Yerevan city.

From Fig. 3 it is evident that the effective sunrise takes place at 9:30 o'clock in the morning. The Fig. 2 displays that at the same 9:30 o'clock the temperature of outside air rises up to $t_{out}=-10$ °C, which is too low for water heating. That is why it is more probable that flat solar heater starts operating in water heating regime at 10:00 o'clock, after sunrise, when intensity of solar radiation reaches to $I=655$ W/m^2 (see Fig. 3) and ambient temperature becomes $t_{out}=-7$ °C. The mentioned combination of irradiance $I=655$ W/m^2 and outside temperature $t_{out}=-7$ °C conditions thermal characteristics of flat plate solar water heater.

4. Determination of Thermal Characteristics of Flat Plate Solar Water Heater

In the early morning, before sunrise, there is not solar irradiance, penetrating into hotbox. As a result, the internal surface and ambient temperatures of hotbox are equal to outside air temperature t_{out} that in wintertime cold climate of Armenia makes $t_{out}=-19$ °C. In the morning, after sunrise, solar radiation penetrates through glass cover and is absorbed by dark colored absorber sheet. The following production allows quantifying solar energy $Q_{sol.in}$, W, that penetrates into narrow hot tunnel:

$$Q_{sol.in} = FI\chi P, \quad (2)$$

where:

F-surface of glazed cover, m^2 ,

I-solar radiation intensity, for 40° northern latitude (Armenia),

$P=0.95$ - solar rays absorption rate by dark colored inside surface of the narrow hot tunnel [3].

The Fig. 3 shows that from 10:00 o'clock to 15:00 o'clock the intensity of solar radiation fluctuates and at 12:30 o'clock rises up to $I=850$, W/m^2 and the average intensity of solar radiation at that period stays on the level $I=750$, W/m^2 .

Daily average intensity of solar radiation equals to $I_{av.}=450$ W/m^2 [2] that is typical for 40° northern latitude.

Because of partial reflection of incident solar rays from glass cover and dust level on its surface, the penetration rate of radiation through single pane glass cover makes $\chi = 0.64$ [3]. Sizes of hot tunnel of the flat plate solar water heater are assumed as follows: the length $a=1$ m, the width $b=0.24$ m (equal to the diameter of 180° bend of water tube) and height of narrow air tunnel $h_{air.tun.}=0.05$ m, the surface of the transparent glass cover is $F=0.24$ m^2 .

According to formula (2) the following quantity of solar energy $Q_{sol.in}$, W, penetrated into the hotbox is determined by the following production:

$$Q_{sol.in} = FI\chi P = 0.2 \cdot 655 \cdot 0.64 \cdot 0.95 = 95.6 \text{ W}$$

As a result the absorber sheet and air in the tunnel acquire so called radiation conditional temperature $t_{cond.}$, $^\circ C$, which is determined by the following formula [4]:

$$t_{cond.} = \frac{I\chi P}{\alpha_{in}} + t_{out}, \quad (3)$$

where:

α_{in} - Convective heat exchange rate on internal surface of the narrow hot tunnel, $W/(m^2 \cdot ^\circ C)$.

5. Evaluation of Convective Heat Exchange Rate on Internal Surface of the Narrow Hot Tunnel

Formula (3) shows that for finding absorber sheet temperature the value of convective heat exchange rate on internal surface of hot tunnel α_{in} is needed. For this purpose, the following formula from similarity theory is used [5, 6]:

$$\alpha_{in} = \frac{Nu \cdot \lambda_{air}}{h_{air.tun.}}, \quad (4)$$

where:

Nu -dimensionless Nusselt criterion (number),

λ_{air} -heat conductivity coefficient of air, $W/(m \cdot ^\circ C)$,

$h_{air.tun.}$ - characterizing dimension of hot tunnel, m.

The value of Nu depends on the regime of air movement. In bounded spaces like hot tunnel with horizontally laid tubes, the movement of air takes place in laminar regime, in case of which the Nusselt number is evaluated by the following equation [5, 6]:

$$Nu = 0.133Gr^{0.33} Pr, \quad (5)$$

where:

Gr - dimensionless criterion (number) of Grasshof.

Pr - Prandtl number. For air $Pr=0.7$.

The following expression presents the Grasshof number:

$$Gr = g\beta t_{air} \frac{l^3}{\nu^2}, \quad (6)$$

where:

g - Acceleration due to gravitation force, $g=9.8$ m/s^2 ,

$\beta=0.0032$ - rate of cubical expansion of air in the range of temperatures 0 to $100^\circ C$ [7],

l - characteristic dimension of hot tunnel, m,

ν - kinematic viscosity of air, $\nu = 0.00001416$ m^2/s .

6. Water Final Temperature in Water Tube

Assuming that whole the heat $Q_{sol.in} = 95.6$ W passes to the water, flowing in water meander tube the final temperature of water $t_{w.fin}$ can be determined by the help of the following formula:

$$t_{w.fin.} = t_{w.in} + \frac{Q_{sol.in}}{g_w c_w}, \quad (7)$$

where:

$t_{w.in}$ - initial temperature of tap water, $t_{w.in}=10^\circ C$,

g_w - water flow rate in the tube, kg/s,

c_w - specific heat of water $c_w=4180$ $J/(kg^\circ C)$.

If daily demand of hot water makes, for instance, $G_w=120$ kg/day or $g_w=G_w/7$ h= $120/7=17.1$ kg/h, the final temperature of water $t_{w.fin.}$, according to (7), rises from initial $t_{w.in}=10^\circ C$ to the following value:

$$t_{w.fin.} = t_{w.in} + \frac{Q_{sol.in}}{g_w c_w} = 10 + \frac{95.6 \cdot 3600}{17.1 \cdot 4180} = 14.81 \text{ } ^\circ C.$$

The water heating up to $t_{w.fin.}=14.81^\circ C$ indicates that in the hot tunnel the air temperature is higher, than $t_{w.fin.}=14.81^\circ C$. This fact proves the radiation temperature $t_{r.ab.sh}$ of absorber sheet, on the surface of which takes place free convection:

$$t_{r.ab.sh.} = t_{out} + \frac{I\chi P}{\alpha_{out}}, \quad (8)$$

where:

$t_{out}=-7^\circ C$ -outside air temperature at 09:30 in the morning,

$\alpha_{out} = 12$ $W/(m^2 \cdot ^\circ C)$ [3] - free heat convection rate on the surface of absorber sheet.

The equation (8) ascertains the following value of $t_{r.ab.sh.}$:

$$t_{r.ab.sh.} = -7 + \frac{655 \cdot 0.64 \cdot 0.95}{12} = 26.2 \text{ } ^\circ C.$$

Substitute $\beta=0.0032$, $t_{air}=26.2^\circ C$, $l=h_{air.tun.}=0.05$ m and $\nu = 0.00001416$ in equation (6) will determine the following

value for Grasshof number:

$$Gr = g\beta\Delta t_{air} \frac{l^3}{\nu^2} = 9.8 \cdot 0.0032 \cdot 14.3 \frac{0.05^3}{(0.00001416)^2} = 279573$$

Substitute the obtained value of Gr in formula (5) and making calculations will obtain the values of Nusselt and Prandtl numbers production:

$$Nu = 0.133 \cdot 279573^{0.33} Pr = 0.133 \cdot 76.58 \cdot 0.7 = 5.84$$

Consequently, the value of convective heat transfer rate on the surface hot tunnel makes:

$$\alpha_{in} = \frac{Nu \cdot \lambda_{air}}{h_{air,tun}} = \frac{5.84 \cdot 0.025}{0.05} = 2.92 \text{ W/(m}^2 \text{ }^\circ\text{C)}$$

where:

$h_{air,tun}=0.05$ m – height of hot tunnel of flat plate water solar heater.

Substitute obtained values: $I=655$ W/m², $\chi=0.64$, $P=0.95$, $\alpha_{in}=2.92$ W/(m² °C) and $t_{out}=-7^\circ\text{C}$ for data in formula (3) will obtain the value of conditional temperature t_{cond} of air on hot tunnel surface:

$$t_{cond} = \frac{655 \cdot 0.64 \cdot 0.95}{2.92} + (-7) = 129.4 \text{ }^\circ\text{C}.$$

7. Determination of Water Tube Diameter

The inferior diameter of water tube calculates the following formula:

$$d_{tub.inf} = \sqrt{\frac{4 \cdot g_w}{\pi \omega \rho_w}}, \quad (9)$$

where:

$\omega=0.015$ m/s - velocity of movement of the water in tube,
 $\rho_w=1000$ kg/m³ – density of water.

Substitute of above data for values in formula (9) gives the following inferior diameter of water tube:

$$d_{tub.inf} = \sqrt{\frac{4 \cdot 17.1}{3.14 \cdot 0.015 \cdot 1000 \cdot 3600}} = 0.02 \text{ m},$$

The exterior diameter of water tube in 3 mm is bigger, than the inferior diameter $d_{tub.inf}=0.02$ m. That is to say

$$d_{tub.ext.}=0.023 \text{ m or } 23 \text{ mm}.$$

8. Determination of Required Length of Water Meander Tube

For complete transferring of the absorbed $Q_{sol.in}=95.6$ W of solar energy to the water, the tube should have appropriate length l_{tub} , m, which can be determined by the following equation:

$$Q_{sol.in} = \frac{\pi l_{tub} (t_{cond} - t_{w.av})}{A}, \quad (10)$$

where:

$t_{w.av}$ – average temperature of the water, in the meander tube,

A - thermal resistance to the heat transfer from air of hot tunnel to the water in the tube, m °C / W.

The average temperature of the water represents the following fraction:

$$t_{w.av} = \frac{t_{w.fin} + t_{w.in}}{2} = \frac{14.81 + 10}{2} = 12.4 \text{ }^\circ\text{C}. \quad (11)$$

The thermal resistance A to heat transfer from hot tunnel air to the water in cylindrical meander tube is calculated by the following expression [8]:

$$A = \frac{1}{\alpha_{ex} \cdot d_{tub.ext.}} + \frac{1}{2\lambda_t} \ln \frac{d_{tub.ext}}{d_{tub.inf.}} + \frac{1}{\alpha_{int.} \cdot d_{tub.inf}}, \quad (12)$$

where:

$\alpha_{ex.} = \alpha_{in} = 2.92$ W/(m² °C) and $\alpha_{int.} = 80$ W/(m² °C) - convective heat coefficients on external and internal surfaces of water tube,

$\lambda_t=401$ W/(m °C) - coefficient of heat conductivity of copper tube.

Substitution of above data for values of formula (12) and making calculation the following thermal resistance A , m °C /W to heat transfer will obtain:

$$A = \frac{1}{2.92 \cdot 0.023} + \frac{1}{2 \cdot 401} \ln \frac{0.023}{0.02} + \frac{1}{80 \cdot 0.02} = 14.89 + 0.000174 + 0.63 = 15.52 \text{ m}^\circ\text{C/W}$$

Substitute of formals (11) and (12) in the formula (10) and making some simplifications, the following equation is obtained:

$$Q_{sol.in} = \frac{\pi l_{tub} (2t_{cond} - t_{w.fin} - t_{w.in})}{2A}. \quad (13)$$

For determining the required length l_{tub} , m of water tube, the formula (13) is converted into the following equation:

$$l_{tub} = \frac{2AQ_{sol.in}}{\pi(2t_{cond} - t_{w.fin} - t_{w.in})}, \quad (14)$$

For transferring completely the penetrated solar energy to the water, flowing in water tubes, the required length of water meander tube, calculated by (14) will obtain:

$$l_{tub} = \frac{2 \cdot 15.52 \cdot 95.6}{3.14(2 \cdot 129.46 - 10 - 14.8)} = \frac{2967.2}{735.1} = 4 \text{ m}$$

Comparison of water meander tubes' length with existing flat plate solar water heaters' tubes shows that the tube of developed solar heater is much shorter. Consequently, the

suggested flat plate solar water heater is simpler, compacted and cheaper.

9. Design of Heliosystem with Flat Plate Solar Water Heater Units

Considered flat plate solar water heater unit consists of hotbox's frame with sizes $a=1$ m, $b=0.24$ m and height $h_{air.tun}=0.05$ m. In air tunnel of each unit a water heating tube with length $l_{tub.}=4$ m and diameter $d_{tub.ext.}=0.023$ m is laid, which provides $g_w=17.1$ kg/h warm water with temperature $t_{w.fin.}=14.81^\circ\text{C}$. The solar units are connected each to other in form of modules and arrays. The modules are parallel installed separate units. Each of them by inlet of its water tube is connected to a tap water main pipeline, which supplies water with initial temperature $t_{w.in.}=10^\circ\text{C}$. The outlets of water tubes are connected to the warm water collector. With the help of parallel arranged units it is possible to increase the quantity of warm water of the same $t_{w.fin.}=14.81^\circ\text{C}$ temperature. The number of parallel installed modules $n_{par.mod}$ depends on required hourly or daily quantity of hot water, which is determined by the following fraction:

$$n_{par.mod.} = \frac{G_w}{g_w}, \tag{15}$$

where:

G_w – daily required total quantity of hot water, kg/day
 g_w – hourly quantity of water, heated in a flat plate unit, kg/h.

If there is necessity to get elevated temperatures of water the units should be connected each to other in series. For instance, in the second flat plate unit, connected with previous one in series, the inlet temperature of water is the outlet temperature of the previous unit $t_{w.fin.}=14.3^\circ\text{C}$. Such calculation can be realized by using the formula (7) too:

$$t_{w.fin.} = 14.81 + \frac{95.6 \cdot 3600}{17.1 \cdot 4180} = 14.81 + 4.81 = 19.62^\circ\text{C}.$$

where:

14.81°C – final temperature of water at the outlet of the first unit,

4.81°C – water temperature growth in each unit.

Taking into account that all the units are identical, in case of connection in series of n units the global final temperature $t_{w.fin.gl}$ of water will be defined by the following expression:

$$t_{w.fin.gl} = t_{w.fin.1} + (n-1)\Delta t_{each.unit}, \tag{16}$$

where:

$t_{w.fin.gl}$ – global final temperature of water at the outlet of the last unit, connected in series,

$t_{w.fin.1}$ – final temperature of water at the outlet of the first unit,

n – number of all units, connected in series.

$\Delta t_{each.unit}$ – Elevation of water temperature in each next unit, connected in series.

For instance, if $n=8$ units are connected in series, at the outlet of the first unit the temperature of water is $t_{w.fin.}=14.81^\circ\text{C}$ and in each of $(n-1)=7$ units, connected each to other in series the temperature growth will make: $7 \times 4.81^\circ\text{C} = 33.67^\circ\text{C}$. Therefore, the global final temperature of water at the outlet of the last 8th unit will make $14.81 + 33.67 = 48.48^\circ\text{C}$. In case of need of higher temperatures, the number of units, connected in series should be respectively increased.

If there is need for increasing of hot water quantity, can be used the heliosystem with parallel arranged units as shown in Fig. 4.

If there is need for increasing of hot water temperature, can be used the heliosystem with connections of units in series as shown in Fig. 5. The number of unites connected in series is determined by the formula as follows:

$$n = \frac{t_{w.fin.gl.} - t_{w.fin.1}}{\Delta t_{each.unit}} + 1, \tag{17}$$

For selecting the maximum number of solar water heater units that can be connected in series, should be taken into account hydraulic losses in the system [9]

At present, are widely used flat plate solar water heaters, the scheme of which displays the Fig. 6 [10].

Figure 4. Schematic design of heliosystem consisted of parallel-arranged flat plate solar water heating units.

10. Energy Efficiency and Cost Effectiveness of Flat Plate Solar Water Heater New Structure

For evaluating efficiency of suggested flat plate solar water heater, it is important to determine its initial cost. Because a sample of new flat plate solar water heater is not produced yet, there are not practically proved data on initial cost. That is why an attempt has been done to determine new solar heater initial cost by using Armenia market costs of materials and manufactured goods in accordance with main parts of flat plate solar water heater. The costs of different parts of the heater, assessed by materials and labor costs in Armenian market are the followings:

Figure 7. Example of a heliosystem composed with new solar water heater units.

- (1) Aluminum U- shape channel frame made of beams with total length for one unit of flat solar heater – 3 m,
 - cost of 1 m is 5\$/m, so the total cost of the frame - 5\$/m x 3 m=\$15,
 - labor cost for manufacturing of the frame \$10.

Total cost of aluminum U- shape channel frame- \$25

- (2) Aluminum 1.5 mm thick and 0.237 m² bottom plate.

- cost for 1 m² of aluminum plate-4.5\$/m².
- total cost of aluminum plate-4.5\$/m²x0.237 m²=1.1\$/m
- labor cost for mounting of the bottom plate \$5.

Total cost for installing of aluminum bottom plate- \$6.1

- (3) 60 mm thick and 0.2 m² surface thermal insulation layer.

- cost of 1 m² of insulation-2\$/m²,
- total cost of insulation-2\$/m²x0.2 m²=\$0.4.
- labor cost for arrangement of 1 m² of insulation – 2.5\$/m².

Total cost of insulation of the solar heater – 2.5x0.4=\$1.0.

- (4) 1.5 mm thick copper absorber sheet with surface – 0.237 m² and weight – 9 kg.

- market cost of 1 kg of cooper sheet-6.2\$,
- total cost of the absorber material-6.2\$/kgx9 kg=\$55.8.
- labor cost of arrangement of the absorber sheet with surface 0.237 m²-\$10.

Total cost of absorber’s installation - \$55.8+\$10=\$65.8

- (5) 180° bend water meander tube with length 2.5 m:

- cost of 1 m of meander tube 6\$/m.
- total cost of the water meander tube 4\$/m x 2.5 m=\$10.
- labor cost of arrangement of the water meander tube \$10.

Total cost of installation of the water meander tube-\$20

- (6) Glass cover with surface 0.237 m².

- cost of 1 m² of glass cover-6\$/m². Cost of glass cover for the water heater – 6\$/m²x 0.237 m²=\$1.43
- labor cost of arrangement of the glass cover-\$10.

Total cost of installation of glass cover - \$11.43

According to the above assessments, the initial (capital) cost of one unit of developed flat plate solar water heater makes: \$25+\$6+\$6.1+\$1.0+\$65.8+\$20+\$11.43=\$135.3.

There would be also 10% of trivial expenses, which make about \$13.53. Therefore, the total capital cost of one unit of the developed flat plate solar water heater makes \$148.8.

The structure and operation of the heliosystem shows the Fig. 7. The heliosystem consists of three rows of new flat plate solar water heater units. In each row, there are 8 units, connected in series. So, totally 24 units are used for complete heliosystem. Respectively the cost of whole the heliosystem makes 148.8x24=\$3571. The heliosystem prepares 51.3 kg/h of hot water with final temperature $t_{w,fin.}=48.48^{\circ}\text{C}$. Assuming that in winter and summer periods together the heliosystem performs properly in average $Z_d=8$ h/day, the daily production of hot water makes in average $G_{w,day.hot} = 51.3 \cdot 8 = 410.4 \text{ kg/day}$. As a result during a year, consisted of $Z_{year}=295$ days, the heliosystem saves energy the quantity of which can be determined by the following equation:

$$Q_{\text{saved, year}} = \frac{G_{\text{w.day.hot}} c_p (t_{\text{w.fin.}} - t_{\text{w.in}}) Z_{\text{year}}}{3600} \quad (18)$$

Substitute above values for quantities of formula (18) will obtain $Q_{\text{saved, year}}=5500$ kWh/year of yearly saving of energy.

By replacing of gas heating boiler by suggested heliosystem, it is possible to save fuel gas during a year in the quantity, determined by the following calculation:

$$G_{\text{gas}} = \frac{Q_{\text{saved, year}}}{\eta_b Q_{\text{gas}}} = \frac{5500}{0.8 \cdot 9.3} = 739.25 \text{ m}^3/\text{year}$$

where:

$\eta_b=0.8$ - COP of gas boiler

$Q_{\text{gas}}=9.3$ kWh/m³ – natural gas combustion heat.

For purchasing 739.25 m³ of gas the yearly saving of means make 739.25/1000 x \$150=110.9\$ per year. Therefore, the payback period of the proposed heliosystem makes $Y=3571/110.9=32$ year.

The comparison with existing flat plate solar water heaters [11] the payback period of suggested structure of flat plate solar heater is about twice shorter.

11. Conclusions

1. The suggested new method includes new approaches for selection of values of solar radiation and ambient temperature taking into account their simultaneous impact on the main characteristics of flat plate solar water heater.
2. The developed simplified method allows calculating all required thermo-physical and constructive characteristics needed for designing rather productive and efficient flat plate solar water heaters.
3. The detailed analysis of suggested method and obtained results prove rather efficient functionality of solar water heater in very cold climatic conditions with very low outside temperatures.
4. The suggested flat plate solar water heater produces 410 l/day of hot water and can be applied for heat supply to domestic and industrial consumers, which need hot water with temperatures up to 100°C.
5. Farther improvement of hot tunnels' structures can increase energy efficiency of flat solar heaters.
6. Although the payback period of new flat plate solar water heater is almost twice shorter compared to

existing ones, but it is still not enough efficient. Therefore, farther simplifying of structure is needed.
