Abstract: Many literatures reported that neonatal lupus erythematosus and its associated abnormalities mainly, cutaneous lupus lesions, congenital heart block (CHB), hematologic cytopenias, hepatobiliary disease and cardiomyopathy are associated with anti-Ro/SSA and anti-La/SSB antibodies. With skin findings occur in nearly 95% of NLE infants, others reported that 100% of NLE infants with CHB were positive for anti Ro/SSA antibodies and 90.2% of infants with skin NLE were positive for anti Ro/SSA. And long-term follow-up of children with neonatal lupus and their unaffected siblings revealed that 12.24% of NLE children identified definite rheumatic/autoimmune diseases after more than 8 years. *Aim of the study:* The aim of this study was to determine the incidence of positive anti-Ro/SSA and anti-La/SSB antibodies in infants with recurrent prolonged skin lesions and their mothers to determine asymptomatic mothers at risk to develop autoimmune disease. *Subjects and methods:* a total of 90 infants with recurrent prolonged skin lesions below the age of 6 months and their mothers attending pediatric screening and follow up clinic at Al Galaa Teaching Hospital in Cairo, Egypt were investigated for positivity of anti Ro/SSA and anti La/SSB antibodies using enzyme linked immunoassay (ELISA). *Results:* Incidence rate of positive anti Ro/SSA alone and anti La/SSB alone antibodies in infants were 34.4% and 23.3% respectively, and positive both anti Ro/SSA and anti La/SSB antibodies was 21.1%, while in their mothers, positive both anti Ro/SSA and anti La/SSB antibodies was 36.7%. Among the 33 cases with positive antibodies female: male ratio was 2.3:1, and rheumatologic and autoimmune diseases was positive in 14 (42.4%) mothers, while, 19 (57.6%) were asymptomatic mothers, anemia, lymphocytosis, neutropenia with relative lymphocytosis, eosinophilia and thrombocytopenia were found in 6.1%, 9.1%, 3.0%, 9.1% and 12.1% respectively. Liver transaminases were elevated in 4 (12.1%). Positive anti Ro/SSA and anti La/SSB antibodies were statistically significantly correlated with infant age, body weight, body length and head circumference, female sex, infants mothers' rheumatologic and autoimmune diseases, distribution of skin lesions, positive history of steroid containing cream use, and thrombocytopenia. However, both antibodies showed no statistically significant correlation with infant feeding, rate of recurrent skin lesions, anemia, lymphocytosis, neutropenia with relative lymphocytosis, eosinophilia, positive CRP, and elevated ESR. *Conclusion:* our infant cases with prolonged skin lesions with positive anti Ro/SSA and anti La/SSB antibodies with their mothers' especially asymptomatic ones should be investigated and followed up properly for development of NLE and autoimmune diseases.

Keywords: Anti Ro/SSA Antibody, Anti La/SSB Antibody, Cutaneous NLE, Autoimmune Diseases

1. Introduction

Autoantibodies to DNA and non-DNA antigens occur in patients with multisystem autoimmune disease e.g., systemic lupus erythematosus [SLE], rheumatoid arthritis, and Sjögren syndrome [SS]. Non-DNA antigens include three main categories: the Ro group, the La group and the U group comprising U1–U6 small nuclear RNAs [1-3]. The Ro group contains two major different proteins Ro/SSA: a 52 kDa Ro (with two subtypes alpha and beta) and a 60 kDa Ro. While the La group contains only one La/SSB protein: a 48 kDa La. Anti Ro/SSA antibodies are detected in the sera of 30% of patients with SLE, even during preclinical setting; and strongly associated (90%) with some subtypes of SLE, it is also associated with primary Sjögren syndrome (50% to 60%) and with undifferentiated connective tissue disease (UCTD) [4]. NLE encompasses a variety of autoimmune manifestations that results from either congenital trans-placental passage of maternal antinuclear and ribonuclear autoantibodies against the Ro/La RNA-protein complex or to less extent from infant's intrinsic deregulated immune system (Primary infantile SLE). Anti-Ro and anti-La autoantibodies targeting fetal and neonatal tissues (Neonatal Lupus Syndromes) are actively transported into the fetal circulation, leading to clinical manifestations that include potentially life-threatening congenital heart block [5 - 7]. It occurs in infants born to mothers with rheumatic conditions including, but not restricted to, systemic lupus erythematosus. Most clinical manifestations of NLE resolve spontaneously with vanishing of maternal auto-antibodies from the neonatal circulation except congenital complete heart block [8]. However, only 1% of infants with positive maternal autoantibodies develop neonatal lupus erythematosus and some cases are born to asymptomatic mothers who are unaware of their autoimmune disorders and get their seropositivity discovered after an affected infant. Maternal disease activity during pregnancy has been associated with increased frequency of neonatal morbidities and admission to the NICU [7]. Cimaz et al., in their studied 128 infants born from 124 pregnancies in 112 women with anti-Ro antibodies with or without anti-La antibodies. They reported 2 cases (1.6%) of congenital heart block (CHB) and 21 children (16%) developed cutaneous NLE, with laboratory testing showed hematologic abnormalities in 27% of the babies and elevation of liver enzymes in 26% [9].

Sonthheimer et al, found that skin findings occur in nearly 95% of their NLE infants. The eruption, which can occur at birth but more typically within a few weeks after birth, is similar to the lesions of subacute cutaneous lupus erythematosus [10]. The skin eruptions typically, erythematous scaling and annular-polycyclic plaques appear on sun-exposed areas, especially on the head and neck, and often in a malar distribution [11], also, similar plaques may appear on the trunk or extremities [12].

Wei Sun et al, found 100% of NLE infants with CHB were positive for anti Ro/SSA antibodies and 90.2% (46/51) of

infants with skin NLE were positive for anti Ro/SSA [12]. Furthermore, positive anti-Ro and anti-La and hepatic and hematological abnormalities are common in cases with skin involvement [11].

Martin's et al, in their study for long-term follow-up of children with neonatal lupus and their unaffected siblings, they reported that 12.24% (6/49) of NLE children identified definite rheumatic/autoimmune diseases after more than 8 years suggesting that prior to adolescence children with NLE require continued follow-up [13].

The current study hypothesized that autoimmune pathogenic process and connective tissue disorders e.g., NLE, could be a cause for recurrent prolonged skin lesions in infants especially below the age of 6 months. The aim of this study was to determine the incidence of positive anti-Ro/SSA (60kDa and 52kDa) and anti-La/SSB antibodies (being are directly involved in the pathogenesis of NLE and other connective tissue disorders), among infants with recurrent prolonged skin lesions attending pediatric screening and follow up clinic at Al Galaa Teaching Hospital in Cairo, Egypt. At the same time to determine the incidence in their mothers to determine asymptomatic mothers at risk to develop autoimmune disease.

2. Subjects and Methods

2.1. Subjects

A total of 90 infants with recurrent prolonged skin eruptions and their mothers from those attending pediatric screening and follow up clinic at Al Galaa Teaching Hospital, in Cairo, were enrolled in this study during 12 months started from March 2017 till March 2018. Inclusion criteria were: Age less than 6 months and Infants with recurrent prolonged skin lesions more than 2 weeks duration in the form of annular-polycyclic erythematous scaling plaques, in face, head, trunk and extremities, Exclusion criteria were: Age more than 6 months, benign neonatal skin lesions and skin lesions less than 2 weeks duration.

2.2. Methods

All participants were subjected to: Full history taking and thorough clinical examination. Electrocardiogram to infants to detect cardiac abnormalities, and Laboratory tests including: complete blood count and differential count using Cell Tac, liver profile by Hitachi 912, erythrocyte sedimentation rate and C-reactive protein, and Measurements of anti Ro/SSA and anti La/SSB for both infants and their mothers by ELISA. A blood sample of 7 ml was obtained by venipuncture from infants, 2 ml were put on EDTA to perform CBC, ESR and 5ml were left to clot and sera obtained were used for liver profiles, CRP, and the rest were stored frozen at -20 until assay of anti Ro/SSA and anti La/SSB. Another blood sample of 3 ml was obtained from mothers, left to clot and sera obtained were stored frozen at -20 until assay of anti Ro/SS-A and anti La/SS-B.

2.3. Assay of Anti Ro/SS-A and Anti La/SS-B

QUANTA Lite SS-B ELISA for the semi-quantitative detection of SS-B antibodies in human serum (INOVA Diagnostics, Inc., cat no 708575).

QUANTA Lite SS-A ELISA for the semi-quantitative detection of SS-A (60kDa and 52kDa) antibodies in human serum (INOVA Diagnostics, Inc., cat no 708570).

Principles of the two Procedures:

Purified SS-B (or SS-A) antigen is bound to the wells of a polystyrene microwell plate under conditions that will preserve the antigen in its native state. Pre-diluted controls and diluted patient sera are added to separate wells; allowing any SS-B or SS-A antibodies present to bind to the immobilized antigen. Unbound sample is washed away and an enzyme labeled anti-human IgG conjugate is added to each well. A second incubation allows the enzyme labeled anti-human IgG to bind to any patient antibodies, which have become attached to the microwells. After washing away any unbound enzyme labeled anti-human IgG, the remaining enzyme activity is measured by adding a chromogenic substrate and measuring the intensity of the color that develops. The absorbance (OD) of each well is read at 450 nm within one hour of stopping the reaction with 620 nm that are used as reference wave length.

Calculation of Results:

The reactivity for each sample can be calculated by dividing the OD of the sample by the OD of the SS-A (or SS-B) ELISA low positive. The result is then multiplied by the number of units assigned to the SS-B (or SS-A) low positive found on the label.

$$\text{Sample value (units)} = \frac{\text{Sample OD}}{\text{SS-B ELISA low positive (OD)(Or SS-A)}} \times \text{SS-B ELISA low positive (units)(or SS-A)}$$

Interpretation of Results:

The ELISA assay was very sensitive to technique and capable of detecting even small differences in patient

populations.

The sample was classified as negative, weak positive, moderate positive or strong positive according to the table below:

Negative	<20 Units
Weak positive	20-39 Units
Moderate positive	40-80 Units
Strong positive	>80 Units

2.4. Statistical Analysis

Results were reported as mean $\pm$ standard deviation (SD) for the quantitative variables and percentages for the categorical variables. The univariate Pearson's chi-square test was used to measure the correlation of each variable with result of positive anti Ro/SS-A and anti La/SS-B in both infants and mothers. P-values of 0.05 or less were considered statistically significant. All statistical analyses were performed using the statistical package for social science (SPSS) version 20.

3. Results

Ninety infants with recurrent prolonged skin lesions and their mothers were enrolled in this study, [53 females and 37 males, with female: male ratio 1.43:1, their mean age = 3.23 ± 1.461 months (mean $\pm$ SD)] and their mothers mean age = 27.13 ± 4.913 years (mean $\pm$ SD). Infants' anthropometric measures were within normal percentiles for age, [BW was 4.52 ± 1.00 kg, length was $59.36 \text{ cm} \pm 4.37$ and head circumference was $39.66 \pm 2.23 \text{ cm}$]. All studied infants had no cardiac symptoms and infants' electrocardiograms (ECG) were normal. The quantitative variables in the studied infants including age of infants and mothers, infant anthropometric measures, and result of laboratory tests including basic laboratory tests and Anti Ro/SSA (60kDa and 52kDa) and anti La/SSB antibodies are shown in Table 1.

Table 1. Basic quantitative variables among all studied cases.

Variables	Range	Mean	Std. Deviation
Infant Age (months)	1 - 6	3.23	1.46
Mother age (years)	20 - 37	27.13	4.91
Infants anthropometric measures:			
BW (kg)	3.000 - 8.000	4.52	1.00
Length (Cm)	54.00 - 70.00	59.36	4.37
Head Circumference (Cm)	36.50 - 45.00	39.66	2.23
Laboratory tests:			
CRP (mg/dl)	1.20 - 24.00	7.64	5.02
ESR (mm)	8 - 24	14.43	4.07
Infant Hemoglobin (gm/dl)	8.80 - 12.20	11.00	1.012
Total WBCs (thousands/cmm)	4370 - 11500	7870.89	2125.64
Neutrophils	1380 - 6260	4117.43	1173.81
Eosinophils	50 - 752	150.74	115.35
Lymphocytes	2045 - 6498	3613.16	979.77
Infant Platelets (thousands/cmm)	75000 - 411000	260566.67	78810.40
Liver enzymes:			
ALT (U/L)	15 - 84	31.08	11.36
AST (U/L)	12 - 71	28.39	10.63
Infants:			
Anti Ro/SSA (U)	2.60 - 53.10	18.54	19.04
Anti La/SSB (U)	2.00 - 47.90	12.45	15.29
Mothers:			
Anti Ro/SSA (U)	2.10 - 49.60	18.49	17.62
Anti La/SSB (U)	1.70 - 53.30	15.76	17.63

Incidence rate of positive anti Ro/SSA and anti La/SSB in infants and mothers was calculated as overall incidence rate of positive antibodies per 100 studied infants and mothers during the study period using the following formula:

$$\frac{\text{No of positive anti Ro/SSA antibodies in infants}}{\text{Total no of studies infants during 12 months}} \times 100 = \frac{31 \times 100}{90} = 34.4\% \text{ per 100 studied infants}$$

$$\frac{\text{No of positive anti La/SSB antibodies in infants}}{\text{Total no of studies infants during 12 months}} \times 100 = \frac{21 \times 100}{90} = 23.3\% \text{ per 100 studied infants}$$

$$\frac{\text{No of positive both antibodies in infants}}{\text{Total no of studies infants during 12 months}} \times 100 = \frac{19 \times 100}{90} = 21.1\% \text{ per 100 studied infants}$$

As 33 mothers had positive both antibodies, the incidence rate in the mothers was

$$\frac{\text{No of positive both antibodies in mothers}}{\text{Total no of studied mothers during 12 months}} \times 100 = \frac{33 \times 100}{90} = 36.7\% \text{ per 100 studied mothers}$$

Table 2 and 3 demonstrates the frequency of different variables in all studied infants and within infants with positive anti Ro/SSA and anti La/SSB antibodies. Total of 33 (36.7.2%) infants and their mothers were positive for anti Ro/SSA and anti La/SSB antibodies by ELISA, from whom 19 infants (57.5%) were positive for both antibodies, 12 cases (36.4%) were positive for anti Ro/SSA alone, and 2 infants (6.1%) were positive for anti La/SSB alone with total of 31 (93.9%) infant positive for anti Ro/SSA antibody and 21 (63.6%) infant positive for anti La/SSB antibody as shown in table 3. Within the studies infant 52 cases (57.8%) were breast fed, while, 20 (22.2%) and 18 (20%) cases were formula fed alone and breast fed with formula supplement respectively, The studied infants had positive mother medical diseases in 26 (28.9%) cases, e.g., diabetes mellitus in 5 (5.6%) cases, hypertension in 3 (3.3%) cases, and atopic dermatitis in 4 (4.4%) cases. Rheumatologic and autoimmune diseases in 14 (15.5%) cases including 5 (5.6%) cases of systemic lupus erythematosus, 4 (4.4%) cases of rheumatoid arthritis, 2 (2.2%) cases of Psoriasis and 3 (3.3%) cases of rheumatic fever. Regarding the skin lesions, the distribution of skin lesions among the studied infants were involving one site alone e.g., head, extremities, trunk, or involving more than one site e.g., head and trunk, head and extremities, trunk and extremities or head, trunk and extremities all together with frequency of distribution are shown in table 2 and figure 1 showing some photos for infants with positive antibodies, the skin lesions in all studied infant showed erythema, scaling and crusting.

The recurrence rate of skin lesions were twice in 36 (40%) cases, thrice in 39 (43.3%) and more than three times in 15 (16.7%) cases. Survival rate was 100% and resolving skin lesions rate was 100% with Conservative care and Avoid ultraviolet light exposure with History of use of Skin creams containing steroid was positive in 47 (52.2%) cases. Frequency of positive finding of anemia, lymphocytosis, neutropenia with relative lymphocytosis, eosinophilia and thrombocytopenia were 4.4%, 3.3%, 2.2%, 3.3%, and 4.4% respectively in studied infants.

Acute phase reactant including C-reactive protein (CRP) was positive in 35 (38.9%) cases and erythrocyte sedimentation rate (ESR) was elevated in 47 (52.2%) cases. Liver transaminases, alanine transaminase (ALT) and aspartate transaminase (AST) were elevated in 4 (4.4%) cases among studied infants.

Figure 1. Sample photos for some infants with positive anti Ro/SSA and anti La/SSB antibodies.

Among the 33 cases with positive antibodies, 10 cases (30.3%) were males and 23 cases (69.7%) were females, with female: male ratio 2.3:1, this indicates that higher rate of positive antibodies occurs in female infants. Infants with positive antibodies had no difference regarding breast or formula feeding with formula fed in 12 (36.4%) cases, breast fed with formula supplement, in 10 (30.3%) cases and breast fed in 11 (33.3%) cases. Infants' mother medical diseases in cases with positive antibodies showed positive history for atopic dermatitis in 4 (12.1%) cases, while, positive rheumatologic and autoimmune diseases in 14 (42.4%) cases including 5 (15.2%) cases of systemic lupus erythematosus, 4 (12.1%) cases of rheumatoid arthritis, 2 (6.1%) cases of Psoriasis and 3 (9.1%) cases of rheumatic fever, figure 2.

Figure 2. Relation of anti Ro/SSA and anti La/SSB antibodies to infants' mothers medical diseases.

Regarding skin lesions, infants with positive antibodies had higher frequency for distribution in more than one site being 10 (30.3%) in head and extremities, 13 (39.4%) in head and trunk, 4 (12.1%) in trunk and extremities, and 6 (18.2%)

in head, trunk and extremities figure 3, with frequency for recurrent skin lesions rate being thrice in 16 (48.5%), twice in 9 (27.3%) and more than three times in 8 (24.2%) cases. figure 4.

Figure 3. Relation of anti Ro/SSA and anti La/SSB antibodies to infants' skin lesions distribution.

Figure 4. Relation of anti Ro/SSA and anti La/SSB antibodies to rate of infants' skin lesions recurrence.

Frequency of positive finding of anemia, lymphocytosis, neutropenia with relative lymphocytosis, eosinophilia and thrombocytopenia were 6.1%, 9.1%, 3.0%, 9.1% and 12.1% respectively in infants with positive antibodies. Acute phase reactant including C-reactive protein (CRP) was positive in

18 (54.5%) cases and erythrocyte sedimentation rate (ESR) was elevated in 17 (51.5%) cases. Liver transaminases, alanine transaminase (ALT) and aspartate transaminase (AST) were elevated in 4 (12.1%) cases among studied infants, tables 2 and 3.

Table 2. Frequency of qualitative variables among all studied cases and positive Anti Ro/SSA and Anti La/SSB cases.

Variables		Among all studied cases		Among positive cases

* . Correlation is significant at the 0.05 level (2-tailed).

Figure 5. Relation of anti Ro/SSA and anti La/SSB antibodies to infants' age.

In Table 4 Positive both anti Ro/SSA and anti La/SSB antibodies in studied infants revealed statistically significant negative correlation with infants' age, (p value .018, and .015 respectively), (figure 5), body weight, body length and head circumference, (p values were .006, .014, .009, and .013, respectively) being elevated at younger age range from 2 to 4 months with highest elevation at age of 3 months, the body weight, length and head circumference showed same correlation as they intend to increase normally with advance of age. Also, revealed statistically significant correlation with female sex (p value was .023 and .005), however, anti La/SSB antibody showed statistically significant positive correlation with mother age (p value .033), but anti Ro/SSA antibody showed no statistically significant correlation (p value .327). Also, both antibodies showed no statistically significant correlation with type of infant feeding either breast or formula feeding, (p value .484 and .878) and showed statistically significant positive correlation with infants' mother medical diseases specially rheumatologic and autoimmune diseases, (p value .000). Both antibodies also, revealed statistically significant correlation with distribution of skin lesions that

involving more than one site and positive history of steroid containing cream use, (p value .000 and .019) respectively, however, no statistically significant correlation was found regarding rate of recurrent skin lesions, (p value .218 and .841). Positive antibodies revealed statistically significant correlation with thrombocytopenia, (p value .005 and .017) but, no statistically significant correlation with anemia (p value .092 and .050), lymphocytosis, (p value .933 and .604) neutropenia with relative lymphocytosis, (p value .361 and .433) and eosinophilia, (p value .252 and .116). Regarding acute phase reactants both antibodies revealed no statistically significant correlation with positive CRP, and elevated ESR (p values were .298, .219 and .417, .399 respectively), and statistically significant correlation was found with elevated liver transaminases, (p value .001 and .000). Infant Anti Ro/SSA antibody alone, showed statistically significant correlation with infant anti La/SSB antibody and both mothers' antibodies, (p value .000), the same statistically significant correlation was found regarding infant anti La/SSB antibody alone, with infant anti Ro/SSA antibody and mothers' antibodies.

4. Discussion

Autoimmune diseases are a group of heterogeneous disorders in which the immune system attacks against its own cells, tissues or organs, resulting in an auto inflammatory reaction that could be cytokines/protein mediated, or antibodies mediated with resultant multiple clinical and laboratory aspects [14]. Diseases are more frequent in female gender than in male (78%). Autoantibody mediated diseases can influence the fetus and newborn, because they are from Immunoglobulin G (IgG) type which can cross the placenta and enter the fetal circulation [15]. Many literatures reported that neonatal lupus erythematosus and its associated abnormalities mainly, cutaneous lupus lesions, congenital heart block (CHB), hematologic cytopenias, hepatobiliary disease and cardiomyopathy are associated with anti-Ro/SSA and anti-La/SSB antibodies [16 - 19]. Neonatal Lupus Syndrome (NLS) in infants is a major outcome of mothers with systemic lupus erythematosus that has been reported in many studies [20 - 26]. It is an acquired autoimmune passive disease mediated by maternal antibodies, reported in about 1-2% of infants born to mothers with autoimmune disease with Anti-Ro/SSA, and Anti-La/SSB antibodies [25]. However, some cases occur in children of mothers who have the same autoantibodies but have no symptoms of SLE, and no other autoimmune disease during pregnancy [27]. The pathogenesis of the disease is not completely clear, but is likely to be greater than the simple passage of paired antibodies. It is also necessary that all lupus patients who decide to have a pregnancy should be screened for Anti-Ro/SSA, and Anti-La/SSB. Identifying mothers at risk allows quick treatment before or after birth [28].

This study reported a female: male ratio 2.3:1 with female predominance which was statistically correlated with anti Ro/SSA and La/SSB antibodies in studied infants with recurrent prolonged skin lesions who had positive antibodies, this result is with concordance to results of studies done by Weston et al, Dickey et al, and Dörner et al, who reported that female neonates with NLE had increased incidence of rash, with a female-to-male ratio ranging between 2: 1 and 3: 1 [11, 29, 30], however, the current study result is in discordance with result of Li et al [31], who reported a ratio of female: male 1.05: 1 with no female predominance and Buyon & Clancy who reported that 55% of studied infants with skin rash were females with no female predominance in a study based on data obtained from the large United States national Research Registry of Neonatal Lupus (RRNL) [32]. On the other side Peñate et al and Asboth et al reported that cutaneous NLE more common in male than female babies [33, 34].

In the current study to assess the incidence of anti Ro/SSA and anti La/SSB antibodies in infants who had recurrent prolonged skin lesions 33/90 cases (36.7) with their mothers had positive anti Ro/SSA and anti La/SSB antibodies, with 19 infants (57.5%) of them were positive for both antibodies, 12 cases (36.4%) were positive for anti Ro/SSA alone, and 2 infants (6.1%) were positive for anti La/SSB alone, a result

that is near to result of study done by Wei Sun et al, who found that infants involved in their study with skin NLE were positive for anti Ro/SSA antibody alone in 18 cases (33.33%), anti La/SSB antibody alone in 1 case (1.85%), and both antibodies in 30 cases (55.56%) [12].

The studied infants with positive antibodies had negative mother history for rheumatologic and autoimmune diseases in 19 (57.6%) and positive history in 14 (42.4%) cases, who had systemic lupus erythematosus in 5 (15.2%) cases, rheumatoid arthritis in 4 (12.1%), Psoriasis in 2 (6.1%) and 3 (9.1%) cases of rheumatic fever, this result is in agreement with Wei Sun et al, who found that 24 mothers (44.44%) in their study for infants with skin NLE were asymptomatic, inspite that they were positive for same antibodies as their infants with 30 cases (55.56%) had rheumatologic and autoimmune diseases, (27 cases) had SLE, (1 case) had rheumatoid arthritis, 1 case had Sjögren syndrome. and 1 case. had psoriasis, but the current study have less cases of SLE and no diagnosed cases of Sjögren syndrome [12], also, the study result regarding percentage of asymptomatic mothers with positive antibodies to Ro/SSA and La/SSB groups is with accordance to results of many authors, Li et al and Izmirly et al, who reported that 63.41% and 66% respectively of NLE mothers enrolled in their studies were asymptomatic [31, 35]. However, Rivera et al reported (15.89%) of NLE mothers with positive antibodies were asymptomatic from data obtained from Research Registry of Neonatal Lupus (RRNL), their results were lower and none contrasting with this study finding [36].

This study revealed that skin lesions in cases with positive antibodies (as seen in photos in figure 1), were distributed in head and extremities, head and trunk and whole body in 30.3%, 39.4%, 18.2% respectively, and had statistically positive correlation with positive antibodies this observation was more or less contrasting with result of Wei Sun et al who described cutaneous lesions in the form of annular-polycyclic erythematous plaques, in 51/54 (94.44%) of their studied cutaneous NLE cases, with most affected sites, the face and head in 46 cases (90.20%), the trunk and extremities in 39 (76.47%) cases and 32 (62.75%) cases respectively. In some cases, erythema had spread over the entire body [12]. Also, this result was with agreement with Peñate et al and Asboth et al who described skin lesions in NLE in the form of erythematous annular plaques with slight scaling, with may be urticaria-like, desquamative, occasionally ulcerative and sometimes crusted on the scalp, neck, or face with periorbital distribution, also, plaques appear on extremities or the trunk, which were more common in male than female babies [33, 34]. The cutaneous manifestations of NLE, are transient appearing after birth mostly by the age of 6 weeks and resolve spontaneously with the clearance of maternal autoantibodies from the infant's circulation by the age of 6 months, usually without any sequelae [12, 37, 38]. This study reported that cases with positive antibodies had statistically significant correlation with the use of steroid this in line with Wei Sun et al., who stated that use of topical corticosteroids was helpful in some cases of cutaneous NLE [12].

Percentage of positive hematologic findings in infants with positive antibodies was 13/33 (39.4%) including anemia, lymphocytosis, neutropenia with relative lymphocytosis, eosinophilia and thrombocytopenia with percentage of 6.1%, 9.1%, 3.0%, 9.1% and 12.1% respectively, and positive antibodies was statistically positively correlated with thrombocytopenia these findings are more or less similar to findings of Li et al, who reported in their review of NLE cases hematological abnormalities in 56 (45.5%) cases including with thrombocytopenia, anemia and both thrombocytopenia and anemia in 17 cases (13.82%), in 38 cases (30.89%), and in 12 cases (9.75%) respectively [31], although, the current study reported lymphocytosis, and not lymphopenia, this result is in agreement with Lee who stated that Lymphopenia is a relatively common in SLE adults but is not a characteristic hematologic abnormality of NLE [38]. Infants with hematological abnormalities are usually asymptomatic [39]. Autoantibodies, bind directly to the neutrophil leading to neutropenia, mainly anti Ro/SSA antibody [38]. The hematologic abnormalities (Anemia, thrombocytopenia, and neutropenia) are self-limited. However, severe thrombocytopenia if present, can lead to internal bleeding and poor prognosis.[14] Again the current study result regarding elevated Liver transaminases, alanine transaminase (ALT) and aspartate transaminase (AST) in 4 (12.1%) cases among studied infants with statistically positive correlation with positive antibodies was more or less with agreement with results of Li et al, who reported 21(17.07%) cases presented with transient mild to moderate elevations of transaminases, and also, reported hyperbilirubinemia, cholestatic hepatitis and hepatomegaly in their studied NLE cases [31], but the current study did not report hyperbilirubinemia, cholestatic hepatitis or hepatomegaly. The hepatobiliary abnormalities in NLE cases occur a few weeks or months after birth and resolving thereafter [39].

In this study the BW, length and HC were within normal percentiles for age but revealed statistically significant negative correlation with positive antibodies, this contrasting with result of many authors studying outcome of pregnancy in mothers with SLE who reported growth disturbances such as IUGR at birth [40 - 43], small baby for gestational age (SGA) [44 - 47], and Mokbel et al [48] who reported 22.5% growth retardation rate where, their figure is consistent with those reported from developed countries [49 - 52].

Also, in this study, cases with positive antibodies had positive correlation with mothers rheumatologic/ autoimmune disease with positive antibodies this is contrasting with results of Friedman et al and Cimaz et al in their prospective studies of pregnancies involving mothers with anti-SSA/Ro and/ or anti-SSB/La autoantibodies reported rates of cutaneous NL of 7% and 16%, respectively, both of which were higher than the 2% rates of cardiac NL [53, 9].

This study revealed that positive antibodies showed no statistically significant correlation with type of infant feeding either breast or formula feeding which is in concordance with

study by Klauninger et al [54] who investigated levels of postnatal autoantibodies in infants born to Ro/SSA positive mothers and their correlation to NLE manifestations, by following a cohort of 32 children from birth to 1 year of age with frequent serum sampling and clinical follow-up. They reported that five of the infants developed cutaneous NLE which occurred in breastfed and in non-breastfed infants. Even if the numbers were limited, these observations are in line with this study findings.

Also, this result is contrasting with Askanase et al [55] who stated that although, breast milk from positive mothers for anti Ro/SSA and anti La/SSB antibody has been described to contain IgA and IgG specific for Ro52, Ro60 and La, the levels of these antibodies were low or non-detectable in infants, suggesting that breast feeding was not involved in the development of skin manifestations.

The current study showed that cases with positive antibodies had no statistically significant correlation with acute phase reactants including C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) this is in line with result by Rao et al [56] in their investigation for the specificity and sensitivity of anti La/SSB antibodies to diagnose systemic lupus erythematosus (SLE) and their correlation with clinical manifestations of SLE where they reported that the levels of ESR and CRP did not differ between the positive and negative antibody cases. However their study was carried on adult and this study was on infants.

5. Conclusion

The studied infant cases with prolonged skin lesions with positive anti Ro/SSA and anti La/SSB antibodies with their mothers' especially asymptomatic ones should be investigated properly for NLE and development of autoimmune diseases. More than 96% of NLE patients presented with skin lesions. As NLE is a passively transferred autoimmune disease, however, NLE incidence has not been defined yet may be due to a lack of disease recognition, and the high rate of asymptomatic NLE mothers is unknown; factors like misdiagnosis of this disease, the lack of awareness as well as economic factors may play a role. Thus, pediatricians, and dermatologists, should improve their recognition of the disease to avoid misdiagnosis. In spite of cutaneous lesions of NL are benign, it may be an important risk factor for cardiac manifestations in subsequent offspring, and a predictor for development of autoimmune disease in the infant and the mother in the long-term. So, standard protocol for diagnosis and follow up of cutaneous NLE cases and their mothers should be designed. The sample size was a limitation to this study, so, a larger study should be hold to study the predictors of cutaneous NLE.

Ethics

The present study was conducted in accordance with approval from the Ethics Committee of general organization of teaching hospital and institutes (GOTHI) and Al Galaa

Teaching Hospital. Written informed consent was obtained from all participants mothers of infants enrolled in the study.

Conflicts of Interest

All the authors do not have any possible conflicts of interest.

Abbreviations

ALT: alanine transaminase
 AST: aspartate transaminase
 CHB: Congenital Heart Block
 CRP: C-reactive protein
 DNA: deoxy ribonucleic acid
 ELISA: enzyme linked immunoassay
 ESR: erythrocyte sedimentation rate
 GOTH: general organization of teaching hospital and institutes
 IgG: Immunoglobulin gamma
 kDa: kilo Dalton
 NLE: Neonatal Lupus erythematosus
 NLS: Neonatal Lupus Syndrome
 RNA: ribonucleic acid
 RRNL: Research Registry of Neonatal Lupus
 SD: standard deviation
 SLE: systemic lupus erythematosus
 SPSS: statistical package for social science
 SSA/Ro: Sjogren's Syndrome related antigen A (Anti-Ro Antibody)
 SSB/La: Sjogren's Syndrome related antigen B (Anti-La Antibody)
 UCTD: undifferentiated connective tissue disease
