Antibiotic Resistance Pattern of *Escherichia coli* Isolated from Diarrhoeic and Non-diarrhoeic Under Five Children in Kano, Nigeria. *International Journal of Microbiology and Biotechnology*. Vol. 4, No. 3, 2019, pp. 94-102. doi: 10.11648/j.ijmb.20190403.15

Received: May 21, 2019; Accepted: June 25, 2019; Published: September 10, 2019

Abstract: Antibiotic resistance in bacterial pathogens is a global health challenge linked to high morbidity and mortality. This study was carried out among under-five children attending three major hospitals in Kano State namely: Murtala Muhammad Specialists Hospital (MMSH), Wudil General Hospital (WGH) and Bichi General Hospital (BGH), representing the three senatorial districts. Rectal swab specimens from 400 diarrhoeic and 50 non-diarrhoeic children were collected with a sterile transport swab containing Carry-Blair Medium. These were inoculated onto MacConkey and Salmonella-Shigella Agar and incubated at 37°C for 18-24 hours for isolation of bacteria. Bacterial isolates were subjected to battery of biochemical tests (IMViC and KIA) for the identification of *Escherichia coli*. Antimicrobial susceptibility test (AST) was carried out on *E. coli* isolated using modified Kirby-Bauer method. The findings revealed 74% and 66% *E. coli* recovery from case and control subjects respectively. The AST revealed trimethoprim-sulfamethoxazole 75.1% was the most resisted antibiotic, significantly different between the case subjects (P -value=0.031), 83% were resistant to at least one class of antibiotic, 44.4% resistant to two classes of antibiotics and significantly higher in the control group (P -value=0.006) and 8.0% MDR rate. Female subjects shows higher resistance to the tested antibiotics but the differences were only significant in amoxicillin-clavulanic acid (49.6% versus 32.9%; P -value=0.003) and trimethoprim-sulfamethoxazole (91.7% versus 57.1%; P -value=0.037) in the case and control group respectively. It can be concluded that *E. coli* is the predominant agent associated with diarrhoea in Kano children and high resistance of trimethoprim-sulfamethoxazole is noteworthy. Hence the need to revise the current diarrhoea treatment regimen for Kano children.

Keywords: *Escherichia coli*, Antibigram, Diarrhoeic, Resistance, Kano

1. Introduction

Antibiotics have accelerated the reduction of infectious disease, saving lives of millions of people in the developed and developing world [1]. Antibiotics have limited the spread of infectious diseases and facilitated the execution of

complex medical procedures. While the dependence of modern society on antibiotics has increased, their efficacy is threatened due to naturally occurring process of antimicrobial resistance (AMR). AMR is the resistance developed by microorganism to antimicrobials that was originally effective for treatment of infections caused by those microbes [2, 3]. AMR in bacterial pathogens is a global health challenge

linked to high morbidity and mortality [4]. There has been an increase in the incidence of bacteria resistant to multiple antibiotics commonly used in treatment of infections [5]. The magnitude differ between and within a country and different geographic region [6]. Increased antibiotic resistance in pathogens have potentially catastrophic consequences leading to increased morbidity and mortality [5], growing healthcare cost, prolonged hospital stay, as-well as treatment failure for both developing and developed nations [7, 8]. Antibiotic usage play a central role in the emergence of AMR in developing countries as well as worldwide [5]. Bacteria resistance has been identified to pose a challenge to diarrhoea management. *Escherichia coli* has been identified as the main carrier of antibiotic resistance in a between-species comparison of enteric bacteria isolated from faecal samples [7]. It is increasingly evident that commensal bacteria, animals and environments are reservoir for antibiotic resistance [5], from which pathogenic bacteria can acquire resistance through horizontal gene transfer [4, 8]. Resistant *E. coli* are classified by WHO as one of the seven bacteria of

international concern [9]. According to the Multiple Indicator Cluster Survey (2018), one in five Kano children die before the age of five years. Diarrhoea was implicated as one of the major causes of mortality among under five Kano children [10]. Diarrhoea is estimated to be a leading cause of under-five death globally [11]. It was reported in 2016 that every 60 seconds a child dies due to diarrhoea [12]. The mortality due to diarrhoea among children younger than five years in Kano was estimated to be 15% [13], higher than the national average of 9% [14]. *E. coli* is a sensitive indicator for the surveillance and spread of antimicrobial resistance among pathogens [5]. The aim of the present study was to determine the socio-demography and clinical characteristics of diarrhoeic and non-diarrhoeic under five children in Kano as-well investigate the resistance pattern of *E. coli*. There is paucity of information on antibiotic resistance pattern among Kano under five children, this study provides data on the resistance pattern of *E. coli*, it is envisaged to assist in policy formulation, empirical management and surveillance of resistance among Kano children.

2. Materials and Methods

Figure 1. Map of Kano State Showing locations of the Sampling Sites.

This study was a descriptive cross sectional hospital base study conducted in Kano. Kano is one of the commercial nerve centre of Nigeria located in the Northwest geopolitical zone with 1,818,598 population of children less than five years (Figure 1). The study was approved by Kano state ministry of health with Ref: MOH/Off/797/T.I/186, verbal and written consent was sought from the parent and guardian of the subjects prior to specimen collection. In this present study rectal swab specimens were obtained from subjects from Bichi General Hospital (BGH), Murtala Muhammad Specialist Hospital (MMSH) and Wudil General Hospital (WGH) in Kano based on the population of each senatorial zones whereby each hospital represents each of the senatorial zones and being the zonal headquarters of each zone. Sample size was calculated using Fisher's formula: $N = Z^2 pq / d^2$ for population above 10,000 [15]. Using a prevalence of 40.7% [16], the minimum sample size was calculated as 371. Thereafter, 400 non repetitive rectal swab specimens were collected from diarrhoeic patients (diarrhoea was described by the passage 3 or more loose or watery stool or at least one bloody stool in a period of 24 hours) based on the population of the three senatorial districts; 174 for MMSH, 123 for WGH and 103 for BGH. In addition, fifty rectal swab specimens were collected from non-diarrhoeic age match as controls. Socio-demographic information and clinical characteristics of the subjects were obtained by survey. Specimens were collected with a sterile transport swab stick containing Carry-Blair medium (*Micropoint Diagnostics USA*), by inserting the cotton swab stick into the rectum of the subjects and the specimens were transported to microbiology laboratory of AKTH in less than 6 hours of sample collection. The specimens were cultured onto MacConkey (*Rapid labs, UK*) and then incubated at 37°C for 18-24 hours as described by Procop *et al.* [17]. All Gram-negative, rod shaped, motile bacterium were subculture onto Eosin Methylene blue agar (EMB) (*Rapid labs UK*) and then subjected to a battery of biochemical tests. All Indole positive, Methylred positive, VP negative, Citrate negative Urease negative isolates that produce acid on KIA slants and a green metallic sheen on EMB were identified as species of the genus *E. coli* as described by Procop *et al.* [17].

Antimicrobial susceptibility study was carried out using modified Kirby Bauer method as recommended by CLSI [18] in Mueller-Hinton agar (*Mast group UK*). A panel of 7 antibiotics (All *Oxoid UK*) was tested; Cefuroxime sodium (CXM), Cefotaxime (CTX), Amoxicillin Clavulanic acid (AMC), Ceftazidime (CAZ), Ciprofloxacin (CIP), Gentamycin (CN) and Trimethoprim/sulfamethoxazole (SXT). Results were recorded as Resistant (R) and Susceptible (S comprising intermediate) according to the reference zone of inhibition of each antibiotics as contained in CLSI [18]. Resistance to 3 or more classes of antibiotics was regarded as multidrug resistance (MDR). The association between socio-demographic and clinical characteristics as well as resistance to antibiotics was assessed using chi square tests, implemented using SPSS version 20 (*IBM, Colorado, USA*). A *P*-value of <0.05 was considered indicative of statistically significant differences.

3. Results

A total of 400 diarrhoeic subjects were recruited from BGH, MMSH, WGH and 50 non-diarrhoeic subjects in Kano state, distribution of the socio-demography and clinical characteristics of the subjects presented in Table 1. There were 57.2% (n=229) male and female 42.8% (171) in the case subjects, in the control group, 62.0% (n=31) male and female 38.0% (n=19). Children within 0-12 months age group 43.0% (n=172) were the most recruited in the case and children within age group 24-59 months 38.0% (n=19) were the most recruited in the control subjects with a significant difference (*P*-value=0.003) between the groups. The feeding pattern of the subjects were significantly different within the case subjects (*P*-value=0.005), higher proportion of subjects in the case 176(44.0%) and control 21(42.0%) subjects. Higher number of subject 38.8% had diarrhoea >4 days before presenting to the hospital, 67.5% had acute watery diarrhoea. The predominant other clinical symptoms among the case subjects were fever 233(58.3%) with a statistical difference between the hospital (*P*-value=0.009). From the specimens from 450 subjects investigated, (329/450, 73.1%) *E. coli* were recovered (296/400; 974% and 33/50; 66% in case and control respectively). The distribution of *E. coli* isolation according to the socio-demography and clinical characteristics of diarrhoeic and non-diarrhoeic children in Kano state (Table 2), proportion of female was significantly higher within the case subjects (56.41%, *P*-value=0.016) and more common in subjects within the age group 0-12months (124/400, 37.6%). Solids only feeding pattern was significantly more common among the case subjects (135/400, 45.60%; *P*-value=0.005). Similarly in the control subjects, solids only feeding pattern was more common (17/33, 51.51%), higher proportion of subjects were from >24-59 months age class (14/33, 42.42%) which was statistically different between the age class of the case subjects (*P*-value=0.003). The distribution of antibiotic resistance pattern of *E. coli* isolated from case and control subjects (Table 3). A relatively higher rate of resistance to the tested antibiotics were observed among those recovered from children attending BGH (CTX; 13.95%, AMC; 43.02%, CIP; 10.46% and as well as resistance to 2 classes of antibiotics; 45.35%) and WGH (CAZ; 23.59%, CN; 6.74%, SXT; 84.27% and as well as resistance to a class of antibiotic; 88.76%) but significant different only obtained in trimethoprim-sulfamethoxazole (*P*-value=0.031). All the β -lactam antibiotics were significantly different among the case and control subjects except Cefotaxime. A relatively higher resistance rate was observed among the control subjects than the case except for trimethoprim-sulfamethoxazole (75.7% versus 68.7%). Resistance to at least two classes of antibiotics was significantly higher in the control subjects than the case subjects (66.7% versus 42.0%; *P*-value=0.006). MDR rate of 7.4% was recorded among the case subjects which was higher among subjects from MMSH (8.3%). MDR rate of 12.12% was recorded among the control subjects.

Antibiotic susceptibility pattern of *E. coli* in relation to the socio-demography of case and control subjects (Table 4), female subjects in the diarrhoeic group are relatively more resistant to all the tested antibiotics except for gentamycin, but the differences only significant in amoxicillin-clavulanic acid (49.6% versus 32.9%; P -value=0.003). Likewise in the control group, female tends to be more resistant to all the tested antibiotics except to ciprofloxacin and equal resistance to ceftazidime, the difference is only significant in trimethoprim-sulfamethoxazole (91.7% versus 57.1%; P -value=0.037). Children within 13-24 months age class in the diarrhoeic group are more resistant to β -lactam antibiotics; cefuroxime (18.6%), amoxicillin-clavulanic acid (44.1%) and ceftazidime (20.3%). Significant difference between the diarrhoeic group were observed in trimethoprim-sulfamethoxazole (P -value=0.004) and ceftazidime (P -value=0.049). Similarly among the control subjects, children within 0-12 months age class are more resistant to the tested antibiotics; cefuroxime (75.0%), cefotaxime (33.3%), ceftazidime (91.7%), ciprofloxacin (16.7%) and trimethoprim-sulfamethoxazole (83.3%). Children within age class 13-24 months shows a higher resistance to gentamycin (14.3%) and children with age >24-59 months shows higher resistance to amoxicillin-clavulanic acid (85.7%). The differences in the resistant pattern among the control children was only significant in cefuroxime (P -

value=0.023). There was a significant difference between the case and control in amoxicillin-clavulanic acid (P -value=0.000), ceftazidime (P -value=0.004) and trimethoprim-sulfamethoxazole (P -value=0.034). Children with diarrhoea that are on mixed feeding pattern (breast milk and solid food) show higher rate of resistance to all β -lactam antibiotics; cefuroxime (19.4%), cefotaxime (15.5%), amoxicillin-clavulanic acid (42.6%) and ceftazidime (20.2%). Children on breast milk only displayed higher resistance to ciprofloxacin (12.5%), gentamycin (9.4%) and trimethoprim-sulfamethoxazole (84.4%). The differences in the resistant pattern among the feeding pattern of children with diarrhoea are only significant in trimethoprim-sulfamethoxazole (P -value=0.004). In the non-diarrhoeic group, children on breast feeding only feeding pattern are more resistant to all the tested β -lactam antibiotics except cefotaxime and children with mixed feeding pattern display higher resistance pattern to ciprofloxacin (18.2%), gentamycin (9.1%) and trimethoprim-sulfamethoxazole (90.9%). Significant difference in resistance in relation with feeding pattern of control subjects only observed in cefotaxime (P -value=0.010). There was a statistical significant difference between the feeding pattern in the case and control subjects in cefotaxime (P -value=0.001) and ceftazidime (P -value=0.045).

4. Discussion

Diarrhoea is one of the most common illness and cause of death in young children in Kano and Nigeria [10]. AMR has become one of the world's most pressing public health challenge of this era. Unnecessary use of antibiotics without prescription for treatment of common bacterial infections is considered as one of the leading causes of the emergence of antibiotic resistance in common pathogens like *E. coli*.

The socio-demography and clinical characteristics of the children shows that (42.8% n=171) were females (57.3%, n=229) were males, these findings were similar to the study of Tian *et al.* [19] (58.1% male and 41.9% female), Haghi *et al.* [20] (60.7% male and 39.3% female) and Natarajan *et al.* [21] (63% males and 37% female) who had more male subjects than female. However, this observation is at variance with the study of Farfan-Garcia *et al.* [22], Ifeanyi *et al.* [23] and Shamki *et al.* [23] with 55.6%, 55.0% and 51.3% female dominance in their respective reports. The reason for higher number of male subjects cannot be established but Kano Multiple Indicator Cluster Survey (KMICS, 2018) reported that diarrhoea are more common in male than female children in Kano [10]. The relative higher proportion of the subjects falling within the age group 0-12 months (43.0%, n=172) is in agreement with the study of Farfan-Garcia *et al.* [22], Tian *et al.* [19] and Shamki *et al.* [24], with higher number of subjects from age group 0-12 months. Age group below 12 months had already been established as a potential risk factor for diarrhoea in children [25]. This is at variance with KMICS (2018) with 13-24 months age group having more diarrhoea. However, Haghi *et al.* [20] had more subjects in age group >24-59 months.

Most of the subjects had solids only feeding pattern (44.0%, n=176) in the case subjects, which is similar to the study of Al-Yassari *et al.* [26], with higher number of subjects with artificial feeding pattern. Diarrhoea onset before reporting to the medical facility shows that most subjects (38.8%, n=155) report to the facility in >4 days of passing loose/watery stool, delayed care seeking maybe as a result of the financial status of the parent or distance of their home to the hospital facility, however, it might be as a result of distrust of healthcare services [27] or personal medication and herbal treatment at home before reporting to the medical facility. Most of the subjects had 3-4 loose/watery stool in 24 hours period (48.5%, n=194) with greater proportion of subjects with acute watery diarrhoea 270 (67.5%) which is in agreement with a similar study in Abuja, Nigeria by Ifeanyi

et al. [23] with higher number of children with acute watery diarrhoea which may be due to the quality of water used at home.

In addition to the clinical state of diarrhoea among the subjects, other clinical symptoms that was predominant among the subjects was fever which accounts for 58.3% (n=233), similar to findings of KMICS (2018) with report of high rate of fever among Kano under five children. This present study revealed the overall prevalence of *E. coli* was 74% (n=296/400) in the diarrhoeic group and 66% (n=33/50) proportion was recorded in the non-diarrhoeic group is similar to what was observed in previous study in Kano [16]. The high rate of isolation of *E. coli* from both subjects may be due to the fact that *E. coli* colonizes the gastrointestinal tract of infants' immediately after birth and coexist in good health with man for a mutual benefits [28]. The emergence and spread of AMR has become a major global public health concern [29], the antibiotic susceptibility pattern of *E. coli* from this study shows that 83.0% (n=273/329) of *E. coli* from this study were resistant to at least one class of antibiotics, similar to the finding of Singh *et al.* [5]. The resistance to even a single antibiotic is a cause for concern as it highlights the problem of antibiotic resistance prevalence and the potential reservoir of genes available to pathogens for developing antibiotic resistance. MDR rate of 7.9% (26/329) in this study is at variance with the study of Seidman *et al.* [7] with 32% MDR rate. The MDR in *E. coli* isolates in this study area possibly reflects the spread and emergence of the antibiotic resistance gene pool in general, which may be higher in incidence when wider panels of antibiotics are investigated. Highest resistance was observed in trimethoprim-sulfamethoxazole (75.7% in case subjects and 69.7% in control subjects), is higher than what was reported by Abdullahi *et al.* [16] among *E. coli* isolates from Kano children. The high resistance to trimethoprim-sulfamethoxazole may be due to the indiscriminate use as one of the first line drug in diarrhoea management, which is in agreement with the findings of Ochoa *et al.* [30] they reported 79% resistance to trimethoprim sulfamethoxazole, 73.7% resistance reported from infant by Dhaka *et al.* [31]. However Putnam *et al.* [32] reported 42.5% resistance to trimethoprim-sulfamethoxazole, Shakya *et al.* [33] reported 29% resistance to trimethoprim-sulfamethoxazole, and a much higher resistance pattern (82%) to trimethoprim-sulfamethoxazole was reported by Al-Yassari *et al.* [26] and 97.6% resistance to trimethoprim-sulfamethoxazole reported by Shah *et al.* [34]. Ochoa *et al.* [30] reported that a higher resistance to trimethoprim-

sulfamethoxazole was exhibited by *E. coli* from case subjects than the control subjects. Over 40% of the *E. coli* isolated from subjects were resistant to trimethoprim-sulfamethoxazole and AMC, this could be attributable to user related factors such as self-medication, non-compliance, advertising pressures due to popularity of a particular drug like Augmentin and Septrin (trimethoprim-sulfamethoxazole) which is like a household name in Nigeria. Further to those mentioned, health care givers not carrying out antimicrobial susceptibility testing before antibiotics prescription (maybe due to lack of facility or the understanding of the financial status of the patients) or mothers who bring children to health centres might seek antibiotics not just for the episode of illness, but stockpile the extra antibiotic for that occasion when reaching the clinic might not be so easy due to distance or long queue in hospitals, a survival strategy where access is limited which is common in developing countries. In some cases, friends and families give unexhausted antibiotics to their sick relatives most especially children without understanding the nature of ailment. Resistance to trimethoprim-sulfamethoxazole has been linked to increased resistance to sulphur-potentiated antimicrobials.

The resistance to ciprofloxacin in this study was 7.9%, similar to the findings of Odetoyin *et al.* [35], they reported 7.2% resistance to ciprofloxacin, at variance with the study of Shah *et al.* [34] with 4.8% resistance and Dhaka *et al.* [31], reported 68.4% ciprofloxacin resistance. The least resistance was observed in gentamycin which might be due to the fact that gentamycin is not tolerated through the oral route and may likely be less abused (5.7% resistance in case subjects and 6.1% resistance in control subjects) which is at variance with the findings of Al-Yassari *et al.* [26] who reported 51.3% resistance to gentamycin. The variation in the resistance pattern might be due to differences in antibiotic policy. Higher susceptibility to ciprofloxacin was observed (over 90% susceptibility) but fluoroquinolones are not approved for children because of the immature joints which might pose a damage risk. There is neither a defined position on the effect of age of children on its antibiotic susceptibility pattern to antibiotics nor a defined position on the role of gender. In this study, female population tends to be more resistant to the tested antibiotics with a higher significance rate within age class 13-24 months. Shakya *et al.* [33] found higher resistance among female children than male although the study didn't correlate with age class. Furthermore, *E. coli* bearing transferable R plasmids was more often found to be associated with antibiotic resistance among female than male in a study conducted among children in Greece [36]. However, Sahoo *et al.* [37] found higher antibiotics resistance among male subjects. Singh *et al.* [5] reported equal resistance rate among male and female. Male subjects in the non-diarrhoeic group tends to be more resistant to the tested antibiotics with no significant difference within the age class of subjects.

5. Conclusion

This study revealed that *E. coli* was the predominant isolate which was higher among 0-12 months age group.

There was a higher resistance among *E. coli* recovered from female subjects as well as children attending BGH and WGH. Though gentamycin and ciprofloxacin presents better effects on the isolates, however cefotaxime with relatively close effects is better recommended for the treatment of diarrhea due to the side effects of fluoroquinolones in children and gentamycin not tolerated orally. Hence the need to revise the current diarrhoea treatment regimen for Kano children and smart policy on antibiotics use to address unnecessary prescription of broad spectrum antibiotics prescribed by physicians and other health practitioner to curb the menace of drug resistant strains in the population.

Authors Contribution

SKH, NTD and MB conceive and design the study, SKH collected the samples and performed the laboratory analysis. SKH analysed the data assisted by RRA and ZMK, SKH wrote the manuscript, assisted by NTD. All authors revised the manuscript before final submission.

Acknowledgements

We would like to appreciate the support of the technical head of Microbiology and Parasitology Mallam Nasiru Magaji, Nasiru Dogua and Usman Bichi.
