Abstract: Flexure hinges as the displacement guiding and amplifying mechanism or sensing component are widely used for micro-actuators and sensors. However, the existing flexure hinges, leaf-spring or notch type, cause serious stress concentration which severely weaken the fatigue life of compliance mechanism. Therefore, developing long fatigue life flexure hinges is very important for high working frequency actuators and sensors, such as fast-tool-servo. Corner-fillet leaf-spring type flexure hinge could provide large displacement with lower stress. Stiffness expressions of it with both fixed-fixed and fixed-guided boundary conditions are derived by using Castigliano's theorem. The main influence factors for stress concentration are investigated and the formulas of stress concentration factor are obtained in terms of ratio of fillet radius to the minimum thickness. These analytical formulas have been verified by comparing with finite element analysis (FEA) results. Stress-life method is chosen to research the influence of fillet radius on fatigue life and the results indicate fillet radius can improve fatigue life of flexure hinge effectively. The proposed analytical solution is the fundamental of optimal design of a leaf-spring type flexure hinge based mechanism with fatigue life constraints.

Keywords: Stiffness, Stress Concentration, Corner-Fillet, Flexure Hinge, Long Fatigue Life

1. Introduction

Compliant mechanisms are widely used in micro actuator [1-3], micromanipulator [4], displacement amplifier [5], micro/nano positioning stages [6-9], accelerometers [10-12] and sensors [13, 14]. For micro/nano position stage, large stroke and accurate displacement output, which make the displacement amplifying and guiding mechanisms become indispensable parts are two important goals to be achieved [15, 16]. Better sensitivity and faster response also make compliance mechanisms important to the sensors. As the basic elements of compliance mechanisms, flexure hinges are mainly divided into two types, notch type and leaf-spring (shown in Figure 1). Notch type flexure hinge is a relative rigid part, with different shapes include conic-section [17, 18], elliptical arc [19], V-shaped [20] and so on. Offering higher rotational accuracy, notch type flexure hinges are utilized for angular output and displacement amplification. Leaf-spring

type flexure hinges can deform as a whole part, which are commonly used for large stroke displacement guidance and sensing elements of sensors.

However, stress concentration often occurs to both leaf-spring type flexure hinges and notch type flexure hinges, which produce high stress level when used for large displacement system. High stress level can lead to a failure of flexure hinge and even the entire compliant mechanisms under dynamic loading conditions [21, 22]. As actuators and sensors working at higher frequency, the fatigue problem becomes extremely important. Therefore, long fatigue life need to be considered in the flexure hinge design. Due to the large displacement output and its popular used in actuators and sensors, corner-fillet leaf-spring type flexure hinges (CFLSFH) are proposed for long fatigue life and large displacement in this paper, and the key work is to develop an analytic expression of the stiffness, and determine an optimal ratio of radius to the minimum thickness under fatigue life constraint.

Figure 1. Existing flexure hinges.

Numerous studies have been made for the design of flexure hinges and compliant mechanism [23-27]. In those literatures, notch type flexure hinges are considered as fixed-free beams, and leaf-spring type flexure hinges are more easily found in fixed-fixed and fixed-guided condition and its design formulas are easily obtained for constant cross-section beam model. Although CFLSFHs are considered as leaf spring for simple design when fillet radius is small, the assumption is inaccurate for large fillet radius CFLSFHs. CFLSFHs are cross-section varying beams, which is far more difficult to obtain the analytic solution of stiffness for either fixed-fixed or fixed-guided condition. To solve this problem, similar researches have been reported by using Castigliano's theorem [28] and inverse conformal mapping [23]. Although the finite element method can analyze the stiffness and fatigue life of a flexure hinge efficiently, it cannot deal with the topology and size optimization simultaneously. Recently, the authors [29] presented a simultaneous optimal design method of topology and size under stiffness and frequency constraints using analytical solution of the equivalent stiffness and mass of flexure hinge. Therefore, the analytical solution of CFLSFHs should be figure out for the further optimizing of guiding mechanism under fatigue life constraints.

In addition, how to design an appropriate fillet to reduce stress and ensure good flexibility and enough deformation area of CFLSFH is another problem need to be solved, which is illustrated in Figure 2 (a) and (b). Although the shape of CFLSFH is similar to corner fillet flexure hinge, their constraints are different. Corner fillet flexure hinges are commonly designed as cantilever beam [28, 30-31], which is shown in Figure 2 (c). So their achievements can't be used for the design of CFLSFH directly. In this paper, the static models of CFLSFH under fixed-guided and fixed-fixed constraint are built and their stiffness equations are deduced based on force method and Castigliano's theorem. The curves of stiffness variation with dimensionless geometric parameters a (ratio of fillet radius to minimum thickness) and b (ratio of hinge length to minimum thickness) are plotted. The influence of main parameters on stress concentration factor is studied and expressions of stress concentration factors are fitted by using finite element analysis results. The stiffness equations and maximum stress predicted by stress concentration factor equations are verified with finite element simulations. Fatigue life of CFLSFH is researched and the case results indicate that fillet can improve the fatigue life effectively.

Figure 2. (a) Fixed-fixed CFLSFH (b) Fixed-guided CFLSFH (c) Corner filleted flexure hinge.

2. Stiffness of CFLSFH

According to Castigliano's theorem [32], the partial derivative of the strain energy of the elastomer with respect to load is equal to the corresponding displacement in the load direction, and it can be stated as:

$$\Delta = \frac{\partial U}{\partial F} \quad (1)$$

where U is strain energy, F is load, and Δ is the corresponding displacement.

When the external loading is applied to flexure hinges, the deformation in load direction can be calculated by Eq.(1). Generally, the leaf-spring type flexure hinge in actuators or sensors can be regarded as Euler-Bernoulli beams (the ratio of length to thickness is greater than 5), where shearing effects are ignored. Under this assumption, the flexible hinge has only

bending deformation under the action of F , and the elastic strain energy is:

$$U = \int \frac{M^2 dx}{2EI} \quad (2)$$

where M is bending moment, E is the elastic modulus, I is the moment of inertia.

The CFLSFH is shown in Figure 3, where l , w , t and r are the length, width, thickness and radius, respectively. Due to the corner-fillets, and thickness is varying with the coordinate X , which can be expressed as:

$$t(x) = \begin{cases} 2(r - \sqrt{r^2 - (r-x)^2}) + t_0, & 0 \leq x \leq r \\ t_0, & r < x < l-r \\ 2(r - \sqrt{r^2 - (x-l+r)^2}) + t_0, & l-r \leq x \leq l \end{cases} \quad (3)$$

Figure 3. Geometric model of CFLSFH.

2.1. Stiffness of Fixed-Guided CFLSFH

The mechanics model of CFLSFH as guiding mechanism is shown in Figure 4, which has fixed-guided boundary conditions.

Figure 4. Mechanical model of fixed-guided CFLSFH.

Figure 5. Statically model of fixed-guided CFLSFH.

The fixed-guided CFLSFH is statically indeterminate to the second degree and therefore two compatibility equations will be necessary for the solution. Choosing support reactions at B as redundant and considering the compatibility of displacement, the flexure hinge then becomes statically determinate and stable. The equivalent statically model is shown in Figure 5.

The expression of bending moment along X axis can be expressed as:

$$M(x) = F\left(\frac{l}{2} - x\right), x \in [0, l] \quad (4)$$

The elastic strain energy is obtained with Eq. (2) and Eq. (8).

The displacement Δ_{fg} of guided end point under the action of F is obtained:

$$\Delta_{fg} = \frac{\partial U}{\partial F} = \int_l \frac{12F\left(\frac{l}{2} - x\right)^2}{Ewt^3(x)} dx \quad (5)$$

Using dimensionless parameters a and b , namely:

$$\begin{cases} a = r/t_0 \\ b = l/t_0 \end{cases} \quad (6)$$

and submitting them into Eq.(5) yields:

$$\Delta_{fg} = \frac{F}{Ew} \left(\frac{6 \arctan(\sqrt{4a+1}) G}{(2a+1)(4a+1)^{5/2}} + \frac{3H}{2(2a+1)(4a+1)^2} + (b-2a)^3 \right) \quad (7)$$

where

$$G = 96a^6 + 128a^5 - 80a^3 - 50a^2 - 12a - 1 + 24a^3b^2 - 24a^3b + 6a^2b^2 - 96a^5b + 24a^4b^2 - 96a^4b$$

$$H = -160a^5 + 32a^4b + 24a^3b^2 + 32\pi a^3 - 32a^4 + 16a^2b^2 + 32\pi a^2 + 72a^3 - 8a^2b + 4ab^2 + 10\pi a + 32a^2 + \pi + 4a$$

Finally, the guiding stiffness can be expressed as:

$$K_{fg} = \frac{F}{\Delta_{fg}} = 2Ew / \left(\frac{6 \arctan(\sqrt{4a+1}) G}{(2a+1)(4a+1)^{5/2}} + \frac{3H}{2(2a+1)(4a+1)^2} + (b-2a)^3 \right) \quad (8)$$

(a)

(b)

Figure 6. Variation of stiffness K_{fg} of fixed-guided CFLSFH with dimensionless geometric parameters. (a) Variation of K_{fg} with a ; (b) Variation of K_{fg} with b .

Figure 6 shows variation of stiffness of fixed-guided CFLSFH with dimensionless geometric parameters. Figure 6(a) indicates that the increase of value of a strengthens the stiffness of fixed-guided CFLSFH, while the increase of value of b slows this trend down. Figure 6(b) demonstrates that the increase of value of b weakens the stiffness of CFLSFH, and the influence of a to stiffness is ignorable when b increases to 40.

2.2. Stiffness of Fixed-Fixed CFLSFH

The mechanics model of fixed-fixed CFLSFH shown in Figure 7, is subjected to concentrated load F at the midpoint.

Figure 7. Mechanical model of fixed-fixed CFLSFH.

Figure 8. Statically model of fixed-fixed CFLSFH.

The fixed-fixed CFLSFH is statically indeterminate to the third degree. Releasing redundant constraints at A and B and considering the compatibility of displacement, statically indeterminate problem can be converted to a statically determinate problem. The equivalent statically model is shown in Figure 8.

The moment formulation along X axis direction can be expressed as:

$$M(x) = \begin{cases} \frac{Fx}{2} - \frac{Fct_0}{8}, & x \in \left[0, \frac{l}{2}\right] \\ \frac{Fl}{2} - \frac{Fx}{2} - \frac{Fct_0}{8}, & x \in \left[\frac{l}{2}, l\right] \end{cases} \quad (9)$$

$$\text{where } c = \frac{(2a+1)(A-B)}{C-D}$$

$$A = \sqrt{4a+1}(64a^4 + 40a^3 - b^2(4a+1)^2)$$

$$B = 48a^3 \arctan \sqrt{4a+1}(2a+1)$$

$$C = \sqrt{4a+1}(64a^4 + 52a^3 + 12a^2 - b(2a+1)(4a+1)^2)$$

$$D = 12a^2 \arctan \sqrt{4a+1}(2a+1)^2$$

The deflection of CFLSFH based on Castigliano's theorem and symmetry principle is shown in Eq. (10).

$$\Delta_{ff} = \frac{\partial U}{\partial F} = 2 \int_0^{\frac{l}{2}} \frac{F \left(\frac{x}{2} - \frac{ct_0}{8} \right)^2}{EI(x)} dx \quad (10)$$

Computing the integral yields:

$$\Delta_{ff} = \frac{F}{Ew} \left(\frac{3I \arctan \sqrt{4a+1}}{4(2a+1)(4a+1)^{5/2}} + \frac{3J}{8(2a+1)(4a+1)^2} + 2 \left(\frac{b}{2} - \frac{c}{4} \right)^3 - 2 \left(a - \frac{c}{4} \right)^3 \right) \quad (11)$$

where

$$I = 3a^2c^2(2a+1)^2 - 24a^3c(2a+1)^2 + 192a^6 + 256a^5 - 160a^3 - 100a^2 - 24a - 2$$

$$J = (6a^2 + 4a + 1)ac^2 + (2a+1)(4a+1)^2\pi - 4a(40a^4 + 8a^3 - 18a^2 - 8a - 1) + 4a^2c(4a^2 - 1)$$

Stiffness of fixed-fixed CFLSFH can be thus expressed as:

$$K_{ff} = \frac{F}{\Delta_{ff}} = Ew / \left(\frac{3I \arctan \sqrt{4a+1}}{4(2a+1)(4a+1)^{5/2}} + \frac{3J}{8(2a+1)(4a+1)^2} + 2 \left(\frac{b}{2} - \frac{c}{4} \right)^3 - 2 \left(a - \frac{c}{4} \right)^3 \right) \quad (12)$$

Figure 9. Variation of stiffness with parameters for fixed-fixed CFLSFH. (a) Variation of K_{ff} with parameter a ; (b) Variation of K_{ff} with parameter b .

Variation of stiffness of fixed-fixed CFLSFH with

parameter is plotted in Figure 9. Figure 9(a) indicates that increasing of the value of a strengthens the stiffness of fixed-fixed CFLSFH, while increasing of the value of b slows the increase trend of stiffness down. Figure 9(b) illustrates that increasing of the value of b weakens the stiffness of CFLSFH, and the influence of a on stiffness is neglectable when b increase to 40.

3. Stress Concentration Factors

The local material reduction of flexible hinge causes an increase of local stress, and the actual maximum stress of flexure hinge is much higher than the predictions of mechanics of materials equations. Stress concentration factor is used to characterize the increase of stress, which is defined as the ratio of actual maximum stress to normal maximum stress. Therefore, stress concentration factor can be used to estimate actual maximum stress of flexure hinge in the design of compliant mechanism, which can be expressed as [34]:

$$k = \frac{\sigma_{\max}}{\sigma_{\text{nom}}} \quad (13)$$

where $\sigma_{\max}$ is actual maximum bending stress, k denotes stress concentration factor and σ_{nom} is normal maximum stress.

3.1. Stress Concentration Factor of Fixed-Guided CFLSFH

For fixed-guided CFLSFH, stress concentration occurs in the connection positions of fillet with straight beam. The moment of fixed-guided CFLSFH in stress concentration part can be evaluated using Eq. (4), and the normal maximum stress can be expressed as:

$$\sigma_{\text{nom}}^{ff} = \frac{M}{I} y_{\max} = \frac{3F(l-2r)}{wt_0^2} = \frac{3F(b-2a)}{A} \quad (14)$$

where $y_{\max}$ represents the maximum distance to the neutral axis of the cross section, A is the sectional area of minimum cross section.

COMSOL software are used to do with FEA of flexure hinges. Ninety models are generated to provide abundant stress results for curve fitting. The main geometric parameters of flexure hinge are $1\text{mm} \leq t \leq 2\text{mm}$, $0.2 \leq a \leq 5$, $40 \leq b \leq 100$. The depth of modeled flexure hinges is 10mm with a Young's modulus (E) of 71.7Gpa and a Poisson ratio (ν) of 0.32. Hexahedral element is chosen to generate the model mesh, which is more accurate than triangle element. Each model is fixed on one end, and roller constraint is added on the other end. The load is applied in the roller end. The maximum stress of every analysis are recorded to calculate stress concentration factor.

Figure 10. FEA model of fixed-guided.

Figure 11. Stress concentration factor for fixed-guided CFLSFH.

The FEA results confirm that the stress concentration factors are dominated by non-dimensional parameter a , while the parameter b has negligible effects on stress concentration factors, as Figure 11 shows. The empirical equation of guiding stress concentration factor k^{fg} is obtained by fitting the results of FEA, as Eq.(15) shows.

$$k^{fg} = 1 + \left(\frac{1.095}{a + 1.0765} \right)^{3.6} \quad (15)$$

According to Figure 11 (b), stress concentration factors are sharply reduced with the increase of a . Stress concentration factors are approximately equal to 1, when a is in the range of 2 to 3. Therefore, [2, 3] is the optimal range of a , synthetically considering the stiffness and stress concentration.

3.2. Stress Concentration Factor of Fixed-Fixed CFLSFH

The moment of fixed-fixed CFLSFH in stress concentration part can be obtained according to Eq. (9). The maximum nominal stress is expressed as:

$$\sigma_{nom}^{ff} = \frac{M}{I} y_{\max} = \frac{3F(ct_0 - 4r)}{4wt_0^2} = \frac{3F(c - 4a)}{4A} \quad (16)$$

The analysis models of fixed-fixed CFLSFH is built using the method similarly to section 3.1. The parameter of models are: $1\text{mm} \leq t_0 \leq 2\text{mm}$, $w=15\text{mm}$, $0.2 \leq a \leq 5$, $40 \leq b \leq 80$. Model of each design is meshed with hexahedral element. Each model is fixed on the both end, and a unit load is loaded at the midpoint of CFLSFH. FEA results for k is calculated using Eq. (13), based on maximum stress of FEA.

Figure 12. FEA model of fixed-fixed CFLSFH.

Figure 13. Stress concentration factor for fixed-fixed CFLSFH.

The FEA results confirm that the stress concentration factors are dominated by non-dimensional parameter a , while the parameter b has negligible effects on stress concentration factors, as Figure 13 shows. The following empirical equations for k^{ff} is obtained by fitting the FEA results.

$$k^{ff} = 1 + \left(\frac{0.385}{a + 0.387} \right)^{2.04} \quad (17)$$

According to Figure 13 (b), stress concentration factors are sharply reduced with the increase of a . Stress concentration factors are approximately equal to 1, when a is in the range of 2 to 3.

4. Verification

The COMSOL software has been utilized to calculate stiffness and stress for the design cases listed in Table 1. The material parameters of models are: $E=71.7GPa$, $\mu=0.32$, $\rho=2810Kg/m^3$. The models built method is same to which is shown in Section 3. Hexahedral element is chosen for higher

accuracy. The load F applied on flexure hinge is 1N.

Table 2 and Table 3 comprises the FEA results and analytical results together with the design parameters of several CFLSFHs in different constrains. The analytical results and FEA results are in good agreement. Compared to FEA results, the maximum errors of stiffness is 2.32%, and the maximum errors of stress is 1.44%.

4	422918	414938	-1.92	7.47	7.33	0.02

5. Fatigue Life of CFLSFH

Fatigue can lead to premature failure of flexure hinge, especially in high frequency and high speed operational situations. Therefore fatigue life is important performance for the vulnerable flexure hinges. The fillet can reduce the stress of CFLSFH and prolong its fatigue life. Stress-life method is used to research the relationship between fillet radius and fatigue life. The fatigue strength of smooth test specimen for Aluminum alloys can be estimate by the following equation [34].

$$S_e = \begin{cases} 0.4S_U & S_U \leq 325MPa \\ 130MPa & S_U \geq 325MPa \end{cases} \quad (18)$$

where S_U is the ultimate tensile strength and S_e is the fatigue strength of material.

The fatigue strength of flexure hinge with no mean stress which account for notch effect, surface finish and preload type, is defined as

$$S'_e = k_a k_b k_c S_e \quad (19)$$

where k_a is the fatigue stress concentration factor, k_b is the surface condition modification factor, and k_c is load modification factor.

The fatigue stress concentration factor can be calculated as

$$\frac{1}{k_a} = 1 + \frac{k_t - 1}{1 + A_p / r} \quad (20)$$

where k_t is stress concentration factor, A_p is material constants, for Aluminum alloys $A_p \approx 0.66$, and r is the radius of curvature.

The surface condition modification factor can be estimated according the surface roughness, which is proposed in [21]. The load factor is defined as

$$k_c = \begin{cases} 1 & \text{bending} \\ 0.85 & \text{axial} \\ 0.59 & \text{torsion} \end{cases} \quad (21)$$

The fatigue safety factor is calculated as

$$S_D = \frac{S'_e}{\sigma_m} \quad (22)$$

where σ_m is normal stress.

Then the fatigue safety factor of CFLSFH in fixed-guided and fixed-fixed condition can be expressed as

$$S_D = \begin{cases} \frac{k_b k_c S_e A}{3F(b-2a) \left(1 + \frac{k^{fg} - 1}{1 + A_p / r}\right)} & \text{for fixed - guided CFLSFH} \\ \frac{4k_b k_c S_e A}{3F(c-4a) \left(1 + \frac{k^{ff} - 1}{1 + A_p / r}\right)} & \text{for fixed - fixed CFLSFH} \end{cases} \quad (23)$$

A case is taken to illustrate the influence of fillet radius to fatigue life of CFLSFH. Consider a given CFLSFH ($t_0=4\text{mm}$, $w=15\text{mm}$) is undergoing a cycling load $F=\pm 100\text{N}$. The compliance mechanism is made of 7075 T6 and manufactured by CNC milling process (surface roughness $R=6.3\mu\text{m}$). The ultimate tensile strength is larger than 325MPa , therefore S_e is 130MPa . k_b can be estimated according surface roughness and is 0.87 . Figure 14 shows that the increase of fillet radius can improve the fatigue life of flexure hinge effectively. In the meantime, boundary condition have obvious influence on the fatigue life of flexure hinge.

(a) Fixed-guided condition

(b) Fixed-Fixed condition

Figure 14. Fatigue safety factor of CFLSFHs.

6. Conclusions

This paper proposes analytic solutions of stiffness of CFLSFH in fixed-fixed and fixed-guided boundary condition, which are widely used in micro-position stages and sensors. The stiffness equations are derived based on Castigliano's theorem and force method. Stress concentration factors of CFLSFHs are investigated according to the analytical results of COMSOL software. Parameter a (ratio of radius to minimum thickness) is verified to be the main influence factor to stress concentration and equations of stress concentration factors are fitted taking a as fitted variable. By confirming stiffness equations and equations of stress concentration factors with COMSOL software, the stiffness errors are less than 3%, and stress errors are less than 2%. Case results indicate that fillet radius can improve fatigue life of CFLSFH effectively. Analytical results of CFLSFHs can be used for the design and further optimization of CFLSFH based mechanism.
