Abstract: Traditionally mushrooms have been used for the prevention and treatment of a multitude disorders. Macro fungi regarding to the development of novel safe antimicrobials and antioxidants has become attractive source for researchers in the last decades. In the present study quantitative analysis of phytochemical constituents was carried out by using standard methods while 1,1 Diphenyl picryl hydroxyl (DPPH) Nitric oxide, Hydrogen peroxide free radical scavenging assay were used to evaluate the antioxidant properties of selected wild mushrooms. Anti-inflammatory capacity of samples was evaluated by HRBC membrane stabilization method. The results obtained from the study revealed that *Agaricus Bosporus* showed higher total phenol, mg flavonoid carotenoid, and lycopene and ascorbic acid contents of (617.9 ± 1) mg/g, (62.52 ± 1.13) mg/g, (74.2 ± 0.057) μ g / mg, (49.6 ± 0.17) μ g / and 28.8 ± 0.34 mg / g. All the species showed antioxidant potential but *Russula delica* proved to be more active while *Agaricus Bosporus*. Proved to be least one.

Keywords: Wild Mushrooms, Scavenging Effect, Total Phenol, Anti-oxidant, Anti-inflammatory

1. Introduction

Mushrooms have received increasing attention, since the primers of human civilization; wild mushrooms have been part of human diet for centuries, mainly because of variety of flavors and tastes they provide. They possess great potential for nutrition, as a rich sources of minerals and having high amounts of water, protein, fiber, and carbohydrates. Lipids are present in low values, which make valuable foods due to low-calorie and low-fat content (Kalac 2009, 2012). This enhances their marketability and economic contribution by approximately two billion dollars (Wang and Hall 2004, Pettenella, Kloehn and 52- 68, 2007). Beyond the nutritional characteristics, a vast body of evidence indicates that mushrooms have been also extensively studied for their medicinal properties, mainly due to their richness in biologically active compounds that presented antioxidant, antimicrobial properties, strengthening the immune system and shielding against carcinogens (Ramesh and Pattar 2010). For the effective treatment of infections the growing emergence of drug-resistant bacterial strains is a serious threat to mankind. It is important to choose the most appropriate antibiotics and to use them appropriately to minimize the development of drug-resistant strains as it is

impossible to prevent bacterial evolution. (Klein Smith and Laxminarayan, 2007). Another significant health issue is stress on the body due to aging, obesity, and detrimental lifestyle choices is, which often takes the form of oxidative damage to tissues. In Human body free radicals are constantly formed, during energy production in the mitochondrial respiratory chain, phagocytosis, fertilization, arachidonic acid metabolism and xenobiotic metabolism. Free radicals such as Super- oxide radicals (O_2^-), hydroxyl radicals ($\cdot OH$) and hydrogen peroxide (H_2O_2) damage DNA, impair enzymes and structural proteins, and provoke uncontrolled chain reactions including lipid peroxidation which leads to the development of cancer, cardiovascular and neurological diseases, cataracts, diabetes, and rheumatoid arthritis. (Circu and Aw, 2010, Jeonget *al.*, 2012). ROS (Reactive oxygen species) are also responsible in development of systemic inflammatory response syndrome, and then they activate nuclear factors thus inducing the synthesis of cytokines. Later, inflammatory mediators and adhesion molecules are also formed. Free radicals react with different cell components at site of inflammation thus leading to loss of function and cell death (Closa and Puy, 2004). However to protect against free radical damage almost all organisms have defense systems which is not sufficient. Many synthetic antioxidants, such as butylated

hydroxyanisole and butylated hydroxytoluene, have side effects and are thought to be responsible for liver damage and carcinogenesis (Grice, 1988).

As a result to prevent oxidative damage and thus protect the human body, natural antioxidants are preferred in food applications. Natural substances, such as vitamins A, C and E, carotenoids, flavonoids and other simple phenolic compounds, are preferred. (Mackerras, 1995). Although there are many studies on nutrient compositions of different mushroom species. The current study sought to investigate the antioxidant and anti-inflammatory activities of wild mushrooms. The antioxidant activity of these mushroom extracts was also assessed by measuring their radical scavenging activity.

2. Material and Methods

2.1. Material

Four mushrooms were selected for the evaluation of antioxidant as well anti-inflammatory

I.e. Agaricus bisporous, Pleurotus Florida, Russula delica, Lyophyllum decastes were obtained from mekelle research center Mekelle Ethiopia

2.2. Determination of Bioactive Compounds

2.2.1. Standard and Reagents

All the Standards solvents other chemicals were of analytic grade.

2.2.2. Phenolic Compound Estimation

100 µl of extract solution was mixed with 1.5 ml of Folin-Ciocalteu reagent and incubated at room temperature for one minute followed by the addition of 1.5 ml sodium carbonate (60g/l). The tubes were then vortex-mixed for 15s and allowed to stand for 90 minutes in dark at room temperature. Absorbance was then measured at 725 nm. Gallic acid was used as standard curve with concentration ranges from 1 to 100 µg/ml ($R^2=0.996$) and the results were expressed as mg Gallic acid equivalent (GAE)/100g DW. All experiments were performed in triplicates. (Singleton *et al.*, 1999)

2.2.3. Flavonoid Contents

250 µl extract of mushrooms was mixed with 1.25 ml of distilled water and 75 µl of a 5% NaNO₂ solution. 150 µl of 10% AlCl₃ · H₂O of was added after 5 min. Then 275 µl of distilled water and 500 µl of 1 M NaOH were added to the mixture after 6 min. The solution was then mixed well and the intensity of pink colour was measured at 510 nm. The flavonoid compounds estimation was carried out in triplicate. Quercetin was used for calibration curve with concentration range of 20-100 µg/ml ($R^2=0.9938$). The results were mean values ± standard deviations and expressed as mg quercetin equivalents (CEs) per gram of extract. (Jia *et al.*, 1999)

2.2.4. Ascorbic Acid Determination

100 mg of dried extracts were extracted with 10 ml of 1%

Meta phosphoric acid for 45 min at room temperature and filtered through Whatman No.4 filter paper. The filtrate (1 ml) were mixed with 9 ml of 2, 6-dichloroindophenol and then absorbance was measured within 30 min at 515 nm against a blank. Content of ascorbic acid would be calculated on the basis of the calibration curve of authentic L-ascorbic with concentration range of 2- 125 µg /ml ($R^2=0.9929$). All the experiments were performed in triplicates. (Klein and Perry, 1982)

2.2.5. β-Carotene and Lycopene Determination

The dried extract (100 mg) was vigorously shaken with 10 ml of acetone-hexane mixture (4:6) for 1 min and filtered through Whatman No.4 filter paper. The absorbance of the filtrate was measured at 453, 505, 645 and 663 nm (Nagata and Yamashita, 1992).

Content of β-carotene and lycopene were calculated by using following equations. Lycopene (mg/100mg) = $-0.0458 A_{663} + 0.372 A_{505} - 0.0806 A_{453}$

β-carotene (mg/100mg) = $0.216 A_{663} - 0.304 A_{505} + 0.452 A_{453}$

2.3. Determination of Antioxidant Capacity

2.3.1. DPPH Free Radical Scavenging Activity

Free radical scavenging activity of mushrooms extracts was determined by DPPH method. 0.1 mM of DPPH solution was prepared in methanol and 0.5 ml of it was added to 0.5 ml of extract. The mixture was vortexed thoroughly and left for 45 minutes in dark at room temperature and absorbance was measured at 515 nm against blank. A lower absorbance represents a higher DPPH scavenging activity. The capability of scavenging DPPH radical was calculated using following equation

$$\text{DPPH scavenging effect (\%)} = (1 - A_s/A_c) \times 100$$

Where A_C is the absorbance of control containing DPPH solution and A_S is absorbance of extract solution containing DPPH. (Hung and Morita, 2009).

2.3.2. Nitric Oxide Scavenging Assay

The interaction of extract of macro fungi with nitric oxide (NO) was assessed by nitrite detection method. The chemical source of nitric oxide was sodium nitroprusside (10 mM) in 0.5 M phosphate buffer pH 7.4 which spontaneously produced nitric oxide in aqueous solution. Nitric oxide interacted with oxygen to produce stable products, leading to the production of nitrites. After incubation for 5 hours at 37°C 0.5 ml of Griess reagent (α-naphthylethylenediamine 0.1 % in water and sulphanilic acid 1 % in H₃PO₄ 5 %) was added. Absorbance of solution was measured at 546 nm. (Tewari *et al.*, 2014)

2.3.3. H₂O₂ Radical Scavenging Assay

A solution of H₂O₂ (40 mM) was prepared in phosphate buffer (7.4 pH). The concentration of H₂O₂ was determined by absorption at 230 nm using spectrophotometer. Extracts (10- 100 µg/ ml) were then added to H₂O₂ solution and after

10 minutes of incubation the absorbance was determined at 230nm. Phosphate buffer without H_2O_2 was used as blank. Ascorbic acid was used as standard curve. (Khaled-Khodja et al., 2014)

2.3.4. HRBC Membrane Sterilization Assay

Blood was collected from healthy volunteer who was not taken NSAID for two weeks. The collected blood was mixed with equal volume of sterilized AL sever solution (2% dextrose, 0.8% sodium citrate, 0.5% citric acid, and 0.42 % sodium chloride in water). The blood was centrifuged at 3000 rpm for 15 minutes. Packed cell were washed with isosaline. Different concentration of extract (100, 250, 500 and 1000 μ g/ ml) were prepared in isosaline. The assay mixture contained 0.5ml of extract 1ml phosphate buffer (0.15M, pH 7.4) 2ml of hypo saline (0.36 %) and 0.5ml HRBC suspension and incubated at 3 C for 30 minutes and then centrifuged at 3000 rpm for 20 minutes. Diclofenac sodium was used as reference standard. Instead of hypo saline 2ml of distilled water was used in control. The haemoglobin content in supernatant solution was estimated using spectrophotometer at 560 nm. (Gandhidasan et, al 1991, Chippada et, al 2011).

%hemolysis was calculated by

%inhibition of hemolysis = $100 (OD_1 - OD_2) / OD_1$

Where,

OD_1 = Optical density of hypotonic buffer saline alone (control).

OD_2 = Optical density of test sample in hypotonic buffer saline solution

3. Results

3.1. Quantitative Phytochemical Analysis

The determination of quantitative phytochemical content of methanolic extracts of selected mushrooms results as given in Table 1 that total contents of phenols ranged between $(240.9 \pm 0.5) - (617.9 \pm 1)$ mg/ g, total flavonoid contents $(39.55 \pm 0.65) - (62.52 \pm 1.13)$ mg/g, total ascorbic acid contents $(19.20 \pm 0.005) - (28.8 \pm 0.34)$ mg/g, total β carotene contents $(49.46 \pm 0.75) - (74.2 \pm 0.057)$ μ g/mg and total lycopene content $(31.4 \pm 0.17) - (49.6 \pm 0.17)$ μ g/mg. The mushrooms *Agaricusbisporous*. Had the highest amount of phenol (617.9 ± 1) mg GAE/g while *Pleurotus Florida* had least amount of phenol present (240.9 ± 0.5) mg GAE/g). Flavonoids and ascorbic acid were also obtained (Table 1) but in small amount in comparison to phenolic compounds while β - carotene and lycopene were found in vestigial amount ($>91 \mu$ g/ g).

Table 1. Bioactive compounds present in different wild mushrooms and commercial cultivated mushrooms.

S.No.	Mushrooms	Phenols(mg/g)	Flavonoids(mg/g)	β - carotene(μ g/mg)	Lycopene(μ g/mg)	Ascorbic acid(mg/g)
1	<i>Agaricusbisporous</i>	617.9 ± 1	62.52 ± 1.13	74.2 ± 0.057	49.6 ± 0.17	28.8 ± 0.34
2	<i>Pleurotus Florida</i>	240.9 ± 0.5	39.55 ± 0.65	49.46 ± 0.75	31.4 ± 0.17	19.20 ± 0.005
3	<i>Russuladelica</i>	465.1 ± 0.9	55.36 ± 0.64	73.6 ± 0.057	48.9 ± 0.34	22.03 ± 0.05
4	<i>Lyophyllumdecastes</i>	267 ± 0.5	44.82 ± 0.65	67.6 ± 0.46	46.1 ± 0.28	20.91 ± 0.005

Results are presented as mean $\pm$ SEM

3.2. Anti -Oxidant Activity

3.2.1. DPPH Free Radical Scavenging Assay

The antioxidant activities of extracts were expressed as

IC₅₀ values of DPPH. The values varied from 342.72 ± 1.21 in *Russuladelica*. To $633.45 \pm 1.66 \mu$ g extracted in *Agaricusbisporous*. As shown in Table 2.

Table 2. IC₅₀ value of extracts of different samples of macro fungi for DPPH, Nitric oxide and H₂O₂ scavenging activity.

S.no.	Macro fungi name	IC ₅₀ (DPPH)	IC ₅₀ (Nitric oxide)	IC ₅₀ (H ₂ O ₂)
1	<i>Agaricusbisporous</i>	633.45 ± 1.66	439.8 ± 1.8	312.74 ± 1.97
2	<i>Pleurotus Florida</i>	649.6 ± 2.41	436.9 ± 2.4	310.34 ± 1.87
3	<i>Russuladelica</i>	342.72 ± 1.21	400.6 ± 1.8	304.39 ± 1.97
4	<i>Lyophyllumdecastes</i>	373.8 ± 0.75	422.2 ± 1.7	307.32 ± 1.91

3.2.2. Nitric Oxide Scavenging Activity

Our finding suggest that all the extracts substantially inhibited nitric oxide production with IC₅₀ value ranges from 400.6 ± 1.8 (*Russuladelica*) to 439.8 ± 1.8 (*Agaricusbisporous*.) as shown in the above Table 2.

3.2.3. Hydroxyl Radical Scavenging Assay

Hydroxyl radical scavenging activity was quantified by measuring the inhibition of the degradation of 2-deoxyribose by free radicals generated by Fenton reaction.

In the present study IC₅₀ value of Hydroxyl radical scavenging activity was calculated and it was observed that the effect on hydrogen peroxide was higher having IC₅₀ value 312.74 ± 1.87 in *Agaricusbisporous* and lower in *Russuladelica* having IC₅₀ value 304.39 ± 1.97 as shown in the above Table 2.

3.2.4. HRBC Membrane Stabilization Assay

The extracts of different mushrooms were studied for their in-vitro anti-inflammatory activity and highest activity was observed in *Agaricusbisporous* and least in *Russuladelica* as shown in Below Table 3.

Table 3. Anti-inflammatory activity of extracts as per HRBC Stabilizing Assay.

S. No.		Concentration used ($\mu\text{g/ml}$)			
	Standard	2500	2000	1500	1000
	Diclofenac sodium	525 $\pm$ 1.25	470 $\pm$ 2.82	410 $\pm$ 2.62	383 $\pm$ 1.82
	Isolates				
1	Agaricusbisporous	342 $\pm$ 0.25	212 $\pm$ 0.30	168 $\pm$ 0.25	125 $\pm$ 0.30
2	Pleurotus Florida	344 $\pm$ 0.5	198 $\pm$ 0.75	148 $\pm$ 0.25	98 $\pm$ 0.30
3	Russuladelica	335 $\pm$ 0.15	174 $\pm$ 0.25	99 $\pm$ 0.15	68 $\pm$ 1.25
4	Lyophyllumdecastes	338 $\pm$ 0.20	210 $\pm$ 0.5	164 $\pm$ 0.25	120 $\pm$ 1.25

Results are presented as mean $\pm$ SEM

4. Discussion

In the present study total phenolic content were estimated by using FolinCiocalteu's reagent.

The reducing power was evaluated by measuring absorbance at 725nm. Flavonoid estimation was done by Ferric chloride method while estimation of Ascorbic acid was done by Meta phosphoric acid method and estimation of β -carotene lycopene was done by method given by Nagata and Yamashita in 1992.

It has been reported earlier that antioxidant activity is well correlated with content of their bioactive compounds especially phenols. Higher content of phenols accounts for better free radical scavenging effect due to their redox properties which can play an important role in absorbing in neutralizing free radicals quenching singlet and triplet oxygen or decomposing peroxides (Mishra et al., 2012). Ascorbic acid is naturally occurring compounds with antioxidant properties and is necessary for wound healing strengthens blood vessels walls. Flavonoids seem to be most promising poly phenolic compound and therefore known to have been a broad spectrum of chemical and biological activities including radical scavenging properties, antiallergenic, antiviral, anti-inflammatory, and vasodilation actions (Pereira et al., 2009 and Parajuli et al., 2012). Thus the extracts of the studied mushrooms may be good alternatives for the treatment of diseases associated with excessive free radical generation and damage. Carotenoids like β - carotene and lycopene exert antioxidant functions such as quenching of singlet oxygen and other electronically excited molecules and progression of many degenerative diseases (Sindhu et al., 2010).

It was revealed in the methanol extracts of mushrooms taken for quantitative analyses of phytochemicals constitute phenols, flavonoids ascorbic acid and β - carotene and lycopene. These compounds possess various antioxidant functions therefore the mushrooms can be harnessed in the management of oxidative stress induced diseases.

Free radicals are known to play a definite role in a wide variety of pathological manifestations therefore, search for natural scavenger of reactive oxygen and nitrogen species seems to be highly desirable to protect against oxidative stress which is responsible for causing numerous diseases.

DPPH being stable free radical has advantage of being unaffected by certain side reactions such as metal ion chelation

and enzyme inhibition. (Amar oweiz et al., 2004). Freshly prepared DPPH exhibit purple deep colour with absorption maximum at 517nm, the deep purple colour of DPPH disappears due to quenching of its free radicals by antioxidants present in the medium i.e. by providing hydrogen atom or by electron donation, via free radical attack on DPPH molecule and convert them to a colourless bleached product, 2,2 diphenyl-1 hydrazine. This reaction results in decrease in absorbance at 517 nm, therefore more rapidly the absorbance decreases the more potent the antioxidant activity of extract. Results of this study suggest that the methanol extracts of mycelia cultures of mushrooms contains phytochemical constituents that are capable of donating hydrogen to a free radical to scavenge the potential damage.

Nitric oxide is free radical present in mammalian cells which are responsible for regulation of various physiological processes but the excess production of NO is associated with several diseases (Ray et al., 2002). Nitric oxide under aerobic condition reacts with oxygen to produce stable products nitrate and nitrite through intermediate NO_2 , N_2O_4 and N_4O_3 . Nitric oxide in higher concentration can be toxic therefore inhibition of nitric oxide is an important goal (Wang et al., 2005).

H_2O_2 has strong oxidizing properties. It occurs naturally at low concentration levels in air, water, human body, plants, microorganism and food (Gulcin, 2005). It can be formed in-vivo by oxidizing enzymes such as superoxide dismutase. It can cross membrane and slowly oxidize a number of compounds. H_2O_2 is rapidly composed into oxygen and water and this may produce hydroxyl radicals ($\cdot\text{OH}$) that can initiate lipid peroxidation and cause DNA damage (Sahreen et al., 2011). Methanol fractions of mushroom's mycelia cultures efficiently scavenged hydrogen peroxide which may be attributed to the presence of phenolic groups that could donate electrons to hydrogen peroxide, thereby neutralizing it into water.

In present study free radical scavenging activity assay of mushrooms were tested using methanol solution of stable free radical, and it was observed that Agaricusbisporous have more appreciable antioxidant activity while Russuladelica have least one. Thus other non-phenolic and flavonoids compound may be responsible for the antioxidant properties of Agaricusbisporous while other may have exhibited their antioxidant activity through different mechanism (Hamzahet. al 2014).

Hypo tonicity induced HRBC membrane lysis i.e. HRBC membrane stabilization was taken as a measure of anti-inflammatory activity. Currently much interest have been paid in the searching of medicinal plants with anti-inflammatory activity which may lead to the discovery of new therapeutic agent that is not only used to suppress the inflammation but also used in diverse disease conditions where the inflammation response is amplifying the disease process.

The vitality of the cells depends on the integrity of their membranes. Red blood cell exposure to hypotonic medium results in lysis of its membrane accompanied by hemolysis and oxidation of haemoglobin (Feirrali et al., 1992). The hemolytic effect of hypotonic solution is related to excessive accumulation of fluid within the cell which results in the rupturing of its membrane. It is therefore expected that compounds with membrane-stabilizing properties, should offer significant protection of cell membrane against injurious substances. The lysosome enzymes released during inflammation produces a variety of disorders. Their extracellular activity is said to be related to acute or chronic inflammation. There is increasing evidence that lysosome enzymes play an important role in the development of acute and chronic inflammation (Prakash et al., 2010). Most of the anti-inflammatory drugs exert their beneficial effects by inhibiting either release of these enzymes or by stabilizing lysosome membrane, which is one of the major event responsible for the inflammatory process.

The extracts exhibited membrane stabilization effect by inhibiting hypo tonicity induced lysis of erythrocyte membrane. The erythrocyte membrane is analogous to the lysosome membrane (Mounnissamy et al., 2008) and its stabilization implies that the extract may stabilize the lysosome membranes. Lysosome membrane stabilization is important in limiting the inflammatory response by preventing the release of lysosome constituents of activated neutrophil such as bactericidal enzymes and proteases, which cause further tissue inflammation and damage upon extra cellular release (Chaitanya et al., 2011). Some of the NSAIDs are known to possess membrane stabilization properties which may contribute to the potency of their anti-inflammatory effect. Though the exact mechanism of the membrane

Stabilization by the extract is not known yet, hypo tonicity-induced hemolysis may arise from shrinkage of the cells due to osmotic loss of intracellular electrolyte and fluid components.

From this result, it is suggested that anti-inflammatory activity observed in this study, may be due to the ability of the extracts to interfere with the early phase of inflammatory reactions, which may stimulate or enhance the efflux of these intracellular components there by exhibits the anti-inflammatory activity.

5. Conclusion

The present study focuses on antioxidant and anti-inflammatory effects of wild mushrooms collected from Mekelle Tigray Ethiopia. These mushrooms are not only consumed but also utilized for their medicinal properties

hence there is a great need to exploit these wild occurring mushrooms from the dense and well expended forests of Tigray to new drug discovery.
