Abstract: *Background:* Mushrooms are important sources of proteins and vitamins, but have unique sensory properties in appearance, flavour and texture that can lead to polarized liking amongst consumers. Children between the ages of 2 to 5 years can be picky eaters and adding vegetables such as mushrooms into their diets can be a challenge. *Objective:* This study involved the development of mushroom-based food products acceptable to children within this age bracket through a stepwise approach. *Materials and Methods:* Sensory attributes of three tropical edible mushrooms, *Pleurotus ostreatus* (EMI), *Pleurotus sajor-caju* (PSCW) and *Auricularia* ssp. (ART), were characterized using quantitative descriptive analysis (QDA), using 30 descriptors. The QDA revealed that all three mushrooms differ distinctly from each other in appearance, mouthfeel and aftertaste. The aroma and flavour profiles of EMI and PSCW mushrooms were comparable. From the QDA, EMI and PSCW were selected and used to formulate six mushroom-based food prototypes; three of which included cereals and the other three had orange-flesh yellow potato flour as main components. The 6 prototype foods were then assessed by three sets of focus groups of caregivers and mothers on the suitability of using the mushrooms in the preparation of foods for children of the target age. Two mushroom-based food products, one with cereal blends and the other with 30% orange flesh yellow potato flour were further subjected to consumer-liking tests involving 83 children 2-5 years old. and this final test established the mushrooms can be incorporated into children's diet. *Conclusion:* The study established two of the mushrooms could be used as flavourant; EMI mushroom suitable for fish or savory-flavoured products whilst the PSCW mushroom was preferred for nutty-flavoured products and these two when used in mushroom-based foods were highly acceptable to children 2 to 5 year old.

Keywords: Edible Tropical Mushrooms, Sensory Attributes, Consumer-Linking Test, Children Aged 2-5 Years

1. Introduction

In most forests areas in Ghana, wild edible mushrooms are regularly collected when in season and used directly as a main source of food or added to dishes such as soups, stews, and teas to enhance flavour and texture. Recently, edible

mushrooms have attracted much interest as functional foods because of their anti-mutagenic, anti-tumoral and anti-viral properties. There are at least 270 species of mushrooms that are known to possess medicinal properties, and regular consumption has potential to benefit an individual's diet. A recent ethno-mycological study conducted in the southern

part of Ghana revealed thirty different mushrooms were collected by consumers, with *Volvariella volvacea*, *Termitomyces* sp., *Coprinus disseminatus*, *Pleurotus tuber-regium*, *Ganoderma lucidum*, *Coprinus disseminatus*, *Schizophyllum commune* and *Daldinia concentrica* being the most used for consumption. [3, 4], Generally, mushrooms are anecdotally thought to reduce obesity, promote weight gain in underweight children, treat asthma, lower blood pressure in hypertensive patients, treat rheumatism, treat diarrhoea and other conditions. It is well acknowledged that underweight, stunting and thinness are serious and widespread nutritional disorders affecting an estimated 16% of young children globally from 2005-2011 and these effects can be reduced through proper nutrition. [7, 8]. The situation is even dire among children Ghana 2 to 5 years old. Attempts at solving the mal-nutritional problems in children have for some time now focused on using cereal and legume blends to produce high quality, high protein infant foods. Unfortunately, these solutions can be costly and efforts are needed to identify alternatives that use fewer of farmers' resources in disadvantaged and poor-resourced communities in Africa.

Given its rich nutrient sources, mushrooms present a unique alternative to the current efforts. They can easily be cultivated using organic agricultural wastes, which are abundant in Ghana and throughout Africa. To introduce children to diets regularly incorporated with mushrooms may require special efforts, given that children between the age groups 2 to 5 are not keen to accept vegetables in the diets. [11], Children at this stage tend to be selective on what foods they like and what they do not like. Getting children to eat nutritious foods can be challenging for mothers and caregivers. There are a wide range of mushrooms with different sensory properties that could provide a rich source of proteins, minerals and fibre. Studies have shown that incorporating consumer insight in the early stages and throughout the development process of food products gives a better chance of success on the market. The objective of this study was therefore to investigate how the sensory attributes of some edible tropical mushroom influence the development of mushroom-based products for children within the age group 2-5 years.

2. Materials and Methods

This study began with using Quantitative Descriptive Analysis (QDA) in order to understand the sensory properties of the three edible mushrooms (*Pleurotus ostreatus* (EMI), *Pleurotus sajor-caju* (PSCW) and *Auricularia* ssp. (ART). This exercise was immediately followed by three focus groups discussions (FGD) involving mothers and caregivers in order to assess their perceptions and attitudes towards using mushrooms in preparing foods for children of age between 2 and 5 years old and finally a consumer-liking test involving 83 pre-school children of the target age.

2.1. Description of the Preparation of the Mushroom-Based Food Samples Used in the Study

Two different mushroom-based products were used in the QDA and the FGD. These are briefly described below.

2.1.1. Preparation of Mushroom Powder Slurry for the QDA

Freshly harvested samples of the three edible mushrooms, *Pleurotus ostreatus* (EMI), *Pleurotus sajor-caju* (PSCW) and *Auricularia* ssp. (ART), were air-dried at $45 \pm 2^\circ\text{C}$ for 9 h to a moisture content 5%, milled into powder and stored in sealed polythene bags and kept in a refrigerator until ready for analysis. To carry out the QDA, slurries of each powdered mushroom were prepared by thoroughly mixing 15 g of the powder in 300 ml of freshly boiled hot water. The slurries were stored in a thermos flask and kept warm at 60°C .

2.1.2. Preparation of Mushroom-Based Food Products for the FGD

Six mushroom-based food products were prepared for the FGD. Two of these six had cereal blends, referred to as Mushroom Cereal Blends (MCB) foods, whilst the other four had orange flesh potatoes (MOFSP), as the main component.

The Mushroom Cereal Blends food products (MCB) used rice, soybean, peanut and mushrooms (EMI and PSCW). The rice grains were cleaned, sorted and roasted for 15 min under low heat in an oven until golden yellow and allowed to cool before use. Peanuts were also cleaned, sorted and roasted in an oven at 190°C for 25 min and allowed to cool. The roasted peanuts were then deshelled in a disc attrition mill and added to the roasted rice, and finally milled using a hammer mill (Brook Crompton Series 2000, Christy Hunt Agriculture Ltd., U. K.) until the desired texture was obtained. Flour from the soybeans was prepared by soaking the beans for 20 min, drained and boiled in water for 30 min. They were then dried in a hot air oven at 65°C to a final moisture content of about 8%. The dried beans were deshelled in a disc attrition mill, winnowed, and milled into smooth flour. The dried milled powders were left to cool at room temperature, and mixed thoroughly using a KitchenAid mixer (Model 5KPM50, KitchenAid, St. Joseph, Mich., U. S. A.) at a slow speed for 2 min, collected in polyethylene bags, and stored at 3 to 5°C until used. The proportions of ingredients for the two mushroom cereal blend formulation are shown in Table 1.

For the Mushroom Orange-flesh Sweet Potato (MOFSP) mash, ingredients used included fresh mature Orange Fleshed Sweet Potato (OFSP) (Jewel CIP 440031), fish (herrings), tomato, onion and the mushroom (EMI and PSCW). The OFSP, obtained through an accredited supplier, were cleaned, sorted, and freeze-dried (Ultra 35 super LE 210247, Virtis Company, Gardiner, NY., U.S.A.) and finally milled into flour that can pass through a 100-mesh sieve. The milled samples were packaged into polyethylene bags, and stored at 3 to 5°C until used. Flour from the fish (herrings) was prepared by roasting the fish and milled until smooth. The fresh tomato was also blanched for 2 min, dried in the freeze dryer for 2 days and milled into smooth flour. Onion powder

was prepared by freeze drying the fresh onion for 2 days and milled into a smooth powder. The dried milled powders of all the ingredients were left to cool at room temperature and thoroughly mixed using a KitchenAid mixer (Model 5KPM50, KitchenAid, St. Joseph, Mich., U. S. A.) at a slow

speed for 2 min. Two different MOFSP-mashes were formulated: One formulation had high percentage (30%) of mushroom and the other formulation had low (5%) percentage of mushroom. Proportions of the different ingredients are as shown in Table 1.

Table 1. Different mushroom-based food products formulated in the study.

Formulation/Type of mushroom	Proportion of components (%)		
Cereal blend	Mushroom powder	Rice-peanut flour ¹	Soybean flour
1 WeanieMix- EM1	10	77	13
2 WeanieMix- PSCW	10	77	13
Orange fleshed sweet potato mash ²	Mushroom powder	OFSP flour	Fish powder
3 Potato- High-EM1	30	45	15
4 Potato-Low-EM1	5	75	10
5 Potato-Low-PSCW	30	45	15
6 Potato- High-PSCW	5	75	10

¹Rice-peanut flour had 72% rice flour and 5% peanut

²Each OFSP-mash formulation had 5% tomato and 5% onion. A pinch of salt can be added during preparation depending on preference

2.2. Investigating the Sensory Attributes of the Three Mushrooms Using QDA.

Samples of the mushroom slurries were served to an 8-member trained QDA panel for assessing of the sensory attributes. Samples were served in triplicate in a complete block randomized method with randomization done across session. The assessment was done in a sensory evaluation laboratory that conforms to ISO 8589 at the Department of Nutrition and Food Science, University of Ghana. The assessors developed individual vocabulary list with definitions to evaluate the samples (Table 2). References were provided to ensure that all assessors were in agreement with the descriptive terms that were generated. Additionally, the assessors rated the intensities of the samples for all the sensory properties on a 15 mm line intensity scale. [15]

2.3. Focus Group Discussion (FGD) with Mothers and Caregivers on the Use of Mushrooms in Food Preparations for Children

Three focus group discussions were conducted to understand perceptions and attitudes of mothers and caregivers in general on the use of mushroom as ingredients in foods for children as well as sensory properties of mushrooms that were desirable in foods for the children. Thus in the FGD, the mothers and caregivers were given the chance to corroborate the findings of the sensory attributes of the three mushrooms as well as test the food concept prototypes made from them. Three focus groups discussions were conducted at three different locations; CSIR-Food Research Institute, Accra (Site 1 - Urban), Somanya Primary School (Site 2 - Rural) and, Department of Nutrition and Food Science (University of Ghana), Accra (Site 3 - Urban).

In each group, between 4 and 9 mothers and caregivers with children aged between 2 and 5 who consented to participate were included with a total number of 24 respondents between the three groups. The duration for each session was between 60 and 90 mins. A laddering approach was used for the interviewing process where follow up questions were based on responses given. At interview Site 2, an interpreter was used to

translate from one local language (Krobo language) to another local language (Twi) before transcription into English. English was used as the language for communication at the remaining two sites. The same moderator conducted all the interviews. To assess the food concept prototypes, six mushroom-based food products (Table 1), as described earlier, were used during the taste sessions of the FGD. [17]

2.4. Consumer-Liking Test Involving 83 Pre-school Children Aged 2-5 Years

Based on the outcome of the FGD, two of the MCB and one of the MOFSP foods were selected for consumer-liking tests involving 83 pre-school children between 2 to 5 years old in the Yilo Krobo District in the Eastern Region of Ghana. These children were selected after permission was obtained from the District Education Service in Yilo Krobo District of Ghana and the parents.

Prior to the actual test, the selected pre-school children were trained over a period of two weeks to be able to hedonically score using coloured cards. For hedonic scale 1= dislike, a Red-coloured card was used. Similarly for the hedonic scale 2 = neither dislike nor like, Blue Card and then for hedonic scale 3 = like, a Green Card was used. Through the promptings of the parents, the child lifted and displayed the card of his/her corresponding to the choice of scale as explained earlier and this was correspondingly recorded as the hedonic score for the child.

Following successful training of the preschool children, two additional weeks were used for the actual tests. One sample of food product was presented to the children in a day in a white bowl, labelled with a unique 3-digit code and the food product was assessed using the developed 3-point hedonic scale scoring using the coloured cards.

2.5. Data and Statistical Analyses

Results for the QDA of the three mushrooms were analyzed by determining mean intensity scores for each attribute. A two-way analysis of variance (ANOVA) for the sample and assessor was done for each attribute using XL-

STAT Pro Software Version 2011 (AddinSoft, France). Correlation between attributes was also done and a product map generated using principal components analysis XL-Stats. Analysis of variance was conducted on the means obtained for the consumer-liking tests using IBM SPSS version 20 (2011). Statistically significant attributes were further analyzed to see where the mean differences exist using Tukey's HSD at 95% confidence interval. Finally, a t-test was used to compare differences in attributes rates for mushroom cereal blend (MCB) and mushroom orange flesh sweet potato (MOFSP) products.

3. Results

3.1. Overall Sensory Profile of the Three Mushrooms

Table 2 shows that the three mushroom, (*Pleurotus*

ostreatus (EMI), *Pleurotus sajor-caju* (PSCW) and *Auricularia* ssp. (ART) could be described and differentiated from each other using 29 sensory attributes under the sensory modalities; appearance, aroma flavour, mouthfeel and aftereffects. Using principal component analyses, a product map as shown in Figure 1 was generated for the three mushrooms. As indicated, all the samples loaded on different spaces on the map. This meant there were distinctly different from each other. EMI was associated with the terms *Ash colour*, *Brown*, *colour*, *Even appearance*, *Milled cereal aroma* and *Boiled crab flavour*. PSCW was on the hand given descriptions such as *Brown colour*, *Cream Colour*, *Fishy Aroma* and *Flour* and *Unami* taste whilst PTR was given descriptors such as *Herbal tea aroma*, *Cold black tea flavour*, *Bitter tastes* and *aftertaste*, *astringent afterfeel* and *chalky mouthfeel* and *aftertaste*.

Table 2. List of descriptors and definitions for sensory properties of the three powdered mushrooms.

Descriptors	Definition	Anchor
Appearance		
Frothy	Aggregation of bubbles on the top.	Not - very
Precipitated	Dispersed nature of particles in water like a chalky suspension (stirring required).	Not - very
Consistency	Degree of viscosity	Thin - thick
Brown colour	Referring to the colour of local tom brown.	Not - very
Cream colour	Referring to the colour of ideal milk.	Not - very
Ash colour	Referring to the remains of burnt charcoal.	Not - very
Clarity*	Clarity of mixture- presence of suspended particles in the supernatant.	Clear - turbid
Evenness*	Relating to the size and arrangement of particles of the sediment.	Smooth - rough
Aroma		
Mushroom1	Characteristic smell of umbrella mushroom- maxims	Not - very
Mushroom2	Characteristic smell of oyster mushroom like boiled cassava or fishy	Not - very
Milled cereals	Characteristic smell of dried milled corn	Not - very
Boiled crab	Characteristic smell of boiled crab water	Not - very
Sea food	Characteristic smell like boiled squid	Not - very
Fishy	Characteristic smell like grouper	Not - very
Herbal tea	Aroma associated with boiled green tea/ neem tree	Not - very
Pungent	Sharp undefined smell	Not - very
Flavour		
Mushroom1	Characteristic taste of umbrella mushroom- maxims	Not - very
Mushroom2	Characteristic taste of oyster mushroom like boiled cassava or fishy	Not - very
Milled cereals	Characteristic taste of dried milled corn	Not - very
Boiled crab	Characteristic taste of boiled crab water	Not - very
Sea food	Characteristic taste like boiled squid	Not - very
Fishy	Characteristic smell like grouper	Not - very
Cold black tea	The taste and feel of cold black tea	Not - very
Bitter	Basic taste	Not - very
Mouthfeel and aftereffects		
Chalky mouthfeel	Feel of particles lingering on the tongue	Not - very
Bitter	Basic taste	Not - very
Chalky	Feel of particles lingering on the tongue	Not - very
Umami	Basic taste	Not - very
Astringent	Basic taste	Not - very

3.2. Discriminating and Important Correlations of the Sensory Attributes

Out of the 29 attributes, 17 of these showed statistically discriminating powers for the sample set and therefore may

be considered as the key descriptive attributes, The colour descriptors, *Ash colour*, *Brown Colour* and *Cream Colour*, were adequate enough to discriminate between the appearance of the three mushrooms. Additional important appearance attributes that were important for distinguishing

between them were *Evenness*, *Consistency* and *Frothy*. For aroma properties, important attributes that could be used to discriminate between the three mushrooms were *Herbal Tea* and *Fishy* whilst *Cold black tea*, *Bitter*, *Milled Cereal* and *Fishy* were the flavour descriptors established by the panel. For the mouthfeel and aftertaste properties, the discriminating descriptors were *Chalky mouthfeel*, and *aftertaste*, *Bitter* and *Unami aftertaste* and *Astringent Afterfeel*.

Two different types of mushroom aroma and flavour were described by the panel; mushroom 1 defined as umbrella mushroom and Mushroom 2 as Oyster mushroom. Although neither of these two terms were significant discriminators between the sample set, important correlations were

observed. There was an association between Umbrella Mushroom Aroma (i.e. mushroom 1) and seafood aroma ($R=0.523$) but this was poorly correlated with seafood flavour ($R=0.309$). Umbrella mushroom flavour was also not strongly correlated with seafood flavour ($R=0.381$). Conversely, oyster mushroom aroma was correlated with fishy aroma ($R=0.543$) as well as with fishy flavour ($R=0.701$). Again, oyster mushroom flavour was strongly correlated with fishy flavour ($R=0.75$). These observations suggest that oyster mushroom aroma follows through into the flavour and is strongly associated with the fishy aroma and flavour while umbrella mushroom aroma, which is associated with seafood aroma does not follow through into the flavour properties of the mushroom.

Figure 1. Product Map of the Three Edible Mushroom with associated Sensory Descriptors.

3.3. Differences in the Sensory Attributes Between the Three Mushrooms: (*Pleurotus ostreatus* (EMI), *Pleurotus Sajor-caju* (PSCW) and *Auricularia ssp.* (ART))

Two-way analysis of variance (ANOVA) with assessor – sample interaction was used to test differences between sample means for the different sensory attributes. Overall, there was statistical significant difference between them for only 7 of the 29 sensory attributes. There was no statistical significant difference between the remaining attributes although significant assessor and interaction effects were detected for several attributes. Some important trends were however observed. These are shown further in the following.

3.3.1. Differences in Appearance Attributes

Figure 2 shows the appearance profile of the sensory mushrooms in a spider plot. There are distinct differences for colour properties; EMI had the most intense *Ash colour*; none of the remaining two samples had *Ash colour*. All three samples had some variations of *brown* and *cream colour*. Although no statistical significant difference was found between mushrooms for *cream colour*; PTR had the highest intensity for this attribute and EMI had the least intensity. A statistical significant difference between samples for *brown colour* was found with PTR showing the lowest intensity for this attribute. There was no statistical significant difference in *brown colour* between EMI and PSCW. PTR was most *frothy* while EMI was the most *even* and had the *thickest consistency*.

Figure 2. Spider plot showing appearance profile for the three mushrooms.

3.3.2. Differences in Aroma Attributes

Figure 3 shows the aroma profile for the three mushrooms in a spider plot. PTR was most intense and distinctly different to the EM1 and PSCW for *herbal tea* aroma. It also had the least *fishy* aroma. Although there was a trend suggesting that PTR was most pungent, this observation was not statistically significantly different. No other statistical

significant differences were found. A trend suggesting that EM1 had *umbrella mushroom* aroma (*mushroom1*) and PSCW had *oyster mushroom* aroma (*i.e. mushroom 2*) was observed. No statistical significance difference was achieved for these two observations as there was a strong interaction effect between assessors and samples.

Figure 3. Spider plot showing aroma profile of the three mushrooms.

3.3.3. Differences in Flavour Attributes

The mean intensity scores for the samples are presented in a spider plot in Figure 4. There was a statistical significant difference between samples for *cold black tea* with PTR rated as the most intense for this attribute. It is important to note

that *cold black tea* flavour was associated with *herbal tea* aroma ($R=0.49$). Although not a statistical significant difference, it is worth noting that PTR was also most bitter in taste. This observation may be due to an association between *cold black tea* and *bitter taste* ($R=0.502$) in this study. Other important trends that did not show statistical significant

difference are that EM1 was most intense for *mushroom 1* (*umbrella mushroom*), *seafood*, *milled cereal* and *boiled crab*

flavours. PSCW was most intense for *fishy* and *mushroom 2* (*oyster mushroom*) flavours.

Figure 4. Spider plot showing flavour profile of the three mushrooms.

3.3.4. Differences for Mouthfeel and Aftereffect Attributes

PTR was distinctly different from the other two samples for mouthfeel and after effect properties as indicated in Figure 5. It was the *chalkiest* in mouthfeel, most bitter aftertaste and with most intense astringent afterfeel. Both EM1 and PSCW had more intense umami aftertaste than PTR.

Figure 5. Mouthfeel and aftereffects of the three mushrooms.

3.4. Results from the Focus Group Discussion

Table 3 shows that the mothers and caregivers were able to detect most of the ingredients used in the preparations of the six mushroom products. They were able to make additional suggestions that helped improve the acceptability of the different mushroom-based food products by the children. Their suggestions clearly depended on the sensory properties established during the QDA.

3.5. Results from the Consumer-Liking Tests Involving 83 Pre-school Children Aged 2-5 Years

Table 4 shows that the overall acceptability of the mushroom cereal blend products was not significantly different from the cereal blend without mushroom. Also, the children liked the taste of the PSCW MOFSP-mash (2.07) more than that of the EM1 MOFSP-mash (1.16). Overall, Table 5 shows that the children preferred the mushroom cereal blend more than the mushroom orange-fleshed sweet potato products.

Table 3. Responses of Mothers and Caregivers to 6 Mushroom-based Products at the 3 Sites Used for the Focus Group Discussion.

Mushroom Product Type	Site	Perceived Ingredients by Mothers and Care givers	Additional Comments by Mothers and Care givers	Possible Relation to the Determined Sensory Attributes of the two selected mushrooms
Weaniemix-EM1	1	Maize, roasted maize flour and mushroom	Add sugar and milk to make more appealing. Salty and can be used as breakfast cereal or evening meal	EM1 was characteristically <i>ash</i> in colour with some <i>brown</i> colour and will make a desirable breakfast cereal
	2	Maize, peanuts mushroom	Add sugar and milk to make more appealing and can be used as breakfast cereal or evening meal	
	3	Rice, maize, peanut, cowpea mushrooms	It is sweet. Children will like it because it can be used as breakfast cereal	
Weaniemix-PSCW	1	Rice, mushroom, maize, peanut and soybean	Add sugar and milk to make more appealing. Children will like it	PSCW was <i>cream</i> coloured with some <i>brown</i> colour and can be

Mushroom Product Type	Site	Perceived Ingredients by Mothers and Care givers	Additional Comments by Mothers and Care givers	Possible Relation to the Determined Sensory Attributes of the two selected mushrooms
Potato- High EM1	2	Maize, soybean, peanut, mushroom, salty, savoury	Our children will like it because it tastes just like traditional weanimix and even better	used interchangeably with EM1 for a breakfast cereal
	3	Maize, soybean, peanut, mushroom, salty, savoury	Not too sweet. Respondents liked and felt their children will like it	
	1	Mushroom, fish powder, mashed, ripe and cooked plantain and maize dough	Appealing appearance, sweet and smooth texture. Nice taste, but has a slight aftertaste	
	2	Herrings, canned tomato puree, palm oil, mushroom	Tasty. More preferred to the alternate sample (Low EM1)	
	3	Fish meal, vegetables like carrots, mushroom	Split opinion (2 respondents felt their children will like it whilst another 2 did not agree) Umami flavor/ taste. Sharp sweetness. Modify by increasing major ingredients and reduce spices that give umami flavor. Texture a little too rough. Good taste	
Potato- Low EM1	1	Taste like mashed, ripe and cooked plantain and maize dough, Yam, fish, shrimp, mushroom sugar	Though positive reactions from respondents, they have however mixed opinions about child acceptance because some say it is not like the normal soup the children know of	Panelist wanted to taste the typical umbrella mushroom flavour and aroma which was not in the low EM1 sample
	2	Taste like sweet yam, fish with carrot and mushroom	Respondents like the aroma but not the taste. Split opinion on child acceptability. Generally less liked than Potato- High EM1	
	3	Fish meal, has vegetables like carrots, Mushroom	Less enthusiasm from respondents. Child acceptability: Sweetness is good and also not too spicy	
Potato-High PSCW	1	Herrings, mushrooms and carrots	Respondents suggested product should be improved for children to accept it	PSCW has typical Oyster mushroom aroma and flavour which was strongly associated with fishy aroma. Fishy aroma has made it less acceptable to caregivers
	2	Peanut and herrings	Less enthusiasm from respondents. One respondent complained this product was so different from the Potato- High EM1 and Potato- Low EM1	
	3	Mushroom, fishmeal and tomatoes	Caregivers believe when the fishmeal is reduced their children will accept it because they like the consistency	
Potato – Low PSCW	1	Mushroom, vegetables like carrots, Fish meal	Caregivers said they liked the consistency and believe their children will like it too	More acceptable than high PSCW because it was reduced in this product hence the fishy flavour and aroma will also be reduced
	2	Taste like mashed, ripe and cooked plantain and maize dough, Yam, fish, shrimp, mushroom sugar	Child acceptability- Split opinions. Whilst some said the consistent thickness will be acceptable to the children, others felt fishy and sour tastes will not make it acceptable	
	3	Mushroom, Fish meal and tomatoes		

Table 4. Mean acceptance scores of mushroom formulations.

Sample code	Mean score for attributes ¹		
	Appearance	Taste	Overall Acceptability
Mushroom Cereal Blend Products			
EM1	2.93a ²	2.87b	2.89a
PSCW	2.87a	2.78ab	2.83a
No mushroom	2.81a	2.66a	2.83a
Mushroom Orange Fleshed Sweet Potato Mash Products			
No mushroom	2.3a	1.55a	1.99ab
EM1	2.19a	1.16b	1.94a
PSCW	2.13a	2.07c	2.20b

¹Sensory attributes were evaluated on a 3-point hedonic scale as follows: 1-dislike, 2- neither like nor dislike, 3-like; ²Mean in the same column followed by different alphabets are significantly different at 5% level of probability;

Table 5. Comparing mean scores for attributes for mushroom cereal blend and MOFSP-mash.

Sample code	Mean score for attributes ¹			
	Appearance	Taste	Overall Acceptability	p-value
Mushroom Cereal Blend Products (X ± SE) ²	2.87 ± 0.02	2.77 ± 0.32	2.85 ± 0.03	0.05

¹Sensory attributes were evaluated on a 3-point hedonic scale as follows: 1-dislike, 2- neither like nor dislike, 3-like. ²Significance associated with student's t-test for attributes.

3. Discussion

Children's eating patterns develop in the early social interactions surrounding feeding. Research has also shown that parents significantly influence their children's early experiences with food and eating habits. Hendy et al (2013) have also explained that mothers and caregivers act as influential socialization agents in shaping children's acceptance of any range of foods presented during their formative period. The results from both our focus groups survey as well as the consumer-liking tests all showed that the target children of the mothers and caregivers in this study ate the same foods as the whole family with slight modifications made to the sensory properties of the foods they eat to help with adaptation to cultural foods. These studies support our observations of the mothers and caregivers in this study who liked the two products and indicated that they will feed their children the mushroom cereal blend as breakfast and the mushroom potato mash as lunch (Table 3).

Parents select the foods of the family diet, serve as models of eating that children learn to emulate, and use feeding practices to encourage the development of culturally appropriate eating patterns and behaviours in children. Children's intake of particular foods is influenced not only by the types of foods present in the home, but also by the amount of those foods available to them. In our current study, mothers and caregivers explained that although mushrooms are suitable ingredients as food, a major limitation for its use as an ingredient is that it is seasonal in Ghana. Research indicates that the extent to which fruits and vegetables are present and readily available and accessible in the home correlates positively with the level of consumption in school-age children. Thus, if mushrooms are available for the home, the level of consumption in the target age group could also increase for the nutritional benefits of the mushroom to be realized.

According to the focus group discussions, most mothers and caretakers were willing to feed their children the two products (Table 3). Wilcock et al (2003) and Guinard (2000) have demonstrated that food consumption behaviour is an index that assesses attitudes towards a food product.[23], A person may like the product but may not be willing to consume it on a regular basis or in large amounts. The focus group discussion revealed that young children in the target areas eat family foods, they do not like to feel discriminated from eating what the whole family is eating. Children's preferences are considered in terms of the sensory properties of the food particularly the level of spiciness (degree of heat or pungency from chilli pepper), even though some children can eat very spicy foods. The sensory properties of food that are important to children's food acceptability are the appearance (colourful), taste, sweet, flavour, spice level and texture (soft). From the focus group discussion, caregivers in the urban area liked the sweetness of the orange flesh sweet potato products and agreed that it is possible that children in

urban regions will have a higher threshold for sweetness acceptance than children in rural areas.

Normal food may be defined as typical of the food prepared for the family. The form in which mushroom is incorporated in foods for children will influence its acceptance. This means for children in the target group, incorporating mushrooms into foods will be most acceptable by processing them so as not to be visible. Caregivers of the target age group may be able to tell if children like a particular food based on prior experience of the food by the child. In some instances the sensory properties of the food may be a cue to determine the acceptance of the food (particularly based on the level of spiciness).

The focus group results suggest that the cereal blend product with mushroom was most acceptable to caregivers although further studies are needed to confirm than the orange fleshed sweet potato products with mushrooms (Table 3). The cereal blend products were considered more normal foods by caregivers and thought to be more acceptable by the target children. The consumer acceptance test with the children confirmed this (Table 4). The attributes for the cereal blend products were significantly ($p \leq 0.05$) more acceptable to the children than the attributes for the MOFSP-mash products (Table 5). There was mixed level of acceptance and mixed opinions on child acceptance for the MOFSP-mash products. Nonetheless, the PSCW MOFSP-mash products had a more positive response from the caregivers compared with the EM1 MOFSP-mash product (Table 3). The consumer acceptability test with the children showed that the children liked the taste of the PSCW MOFSP-mash than the taste of the EM1 MOFSP-mash (Table 4).

4. Conclusions

This study revealed that edible mushrooms *P. ostreatus*, *P. sajor-caju* and *Auricularia spp* have distinct sensory parameters of appearance, mouthfeel and aftertaste; even though the aroma and flavour profiles of the first two were comparable.

In particular, *P. ostreatus*, and *P. sajor-caju* can be used as flavorants in developing mushroom-based food products for pre-school children aged between 2 and 5. *P. ostreatus* is suitable for fish or savory-flavoured products whilst *P. sajor-caju* is good nutty-flavoured products.

Both mushrooms were successfully used in producing a cereal-fortified mushroom and an orange flesh yellow potato flour fortified mushroom foods products for these children.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Acknowledgements

We acknowledge USAID-Partnerships for Enhanced

Engagement in Research (PEER) Science project for supporting the data collection at the Center for Advanced Functional Foods Research and Entrepreneurship, Department of Food Science and Technology at the Ohio State University.
