Abstract: Health benefits of Lentil sprout (LS) have not yet been well documented. In this study, effects of LS consumption on glycemic parameters and anthropometric measurements in overweight and obese patients with type 2 diabetes were investigated. Thirty-nine type 2 diabetic patients were randomly divided into two groups; LS group and controls. Patients in LS group received 60 g lentil sprouts daily, and the patients in control group continued regular diet. Anthropometric measurements, the levels of fasting blood glucose (FBS), hemoglobin A1C (HbA1c), serum insulin, homeostasis model assessment of insulin resistance (HOMA-IR) and quantitative insulin sensitivity check index (QUICKI) were assessed at baseline and after 8-weeks. After 8 weeks, serum levels of HbA1c and HOMA-IR were lower in the LS group compared to control group ($P < 0.05$). The QUICKI also was higher in the LS group compared to controls (0.34 vs. 0.32, $P < 0.05$). The results suggested that LS consumption could have favorable effects on glycemic control in overweight and obese patients with type 2 diabetes.

Keywords: Lentil Sprouts, Type 2 Diabetes, Glycemic Control, Anthropometric Measurements

1. Introduction

Diabetes mellitus is a metabolic disorder characterized by absolute or relative insulin deficiency, hyperglycemia, and disorder in carbohydrate and lipid metabolism [1]. Glycosylated hemoglobin (HbA1c) is an important index in blood glucose controlling in the last 2-3 months [2-4]. Also HbA1c is an independent risk factor for CVDs diseases in people with or without diabetes [5,6]. Due to side effects of drugs which are used to treat diabetes, using complementary therapies and modification of the dietary pattern are good ways to improve the condition of disease. Various studies have shown that legumes consumption has many effects in health improvement, control and protection against metabolic diseases such as type 2 diabetes and CVDs [7]. The fiber content of lentil seed is 3.7 gr per 100 gr; lentil seed also has low glycemic index (21/2). After germination of the lentil seeds, the amount of fiber and protein increased [8]. As the effects of lentil sprouts (LS) on glycemic parameters and anthropometric measurements in diabetic patients with

overweight and obesity have not yet been determined, according to the importance of legumes and cereal sprouts in Iranian traditional medicine, we therefore conducted this trial to investigate the effect of LS on fasting blood glucose, HbA1c, insulin concentration, quantitative insulin sensitivity check index (QUICKI), homeostasis model assessment of insulin resistance (HOMA-IR) and anthropometric measurements in overweight and obese patients with type 2 diabetes.

2. Methods

Methods are presented as blow:

2.1. LS Preparation

The lentil seeds were placed in water for 30 hours. The seeds were placed on a wet cotton tissue. After 24 hours, lentil sprouts were packed and sent to patients. In these stages temperature of environment was 25-30 °C, but after the preparation they were kept in a refrigerator.

2.2. Study Population

Patients [male and female] with type 2 Diabetes, who were referred to the Iran Diabetes society and endocrine clinic of Taleghani medical center, were evaluated for inclusion criteria. This trial was done between September and November 2013. Ethics approval was obtained from ethical committee of Tabriz University of medical science. The trial has been registered in the Iranian Registry of Clinical trial at <http://www.irct.ir> with the following identification IRCT201305251640N9. The patients aged 30-65 years, having body mass index 25-40 kg/m². Patients were defined as type 2 diabetes patients who have been suffered for at least one year. Subjects with renal, hepatic disorders, gestation or lactation and patients who have used insulin injection, contraceptive pills, glucocorticoid drugs or LS and multivitamin and supplements with antioxidant during 3 months before the beginning of the study were excluded. None of the participants used alcohol or tobacco products. Forty-eight subjects (31 men and 17 women) were enrolled and divided into two groups randomly. Subjects in the control group (16 men and 7 women) received only standard drug therapy; however, the LS group (15 men and 10 women) consumed 60-grams of LS per day during 8 weeks with standard drug therapy. Patients in the LS group consumed LS alone or with salad. Subjects provided with written informed consent. For monitoring assess nutrient intakes, three-day dietary recalls including two weekdays and one weekend day were collected at baseline and again after eight weeks from participants. The method of consumption was written for the participants. They were asked to maintain their habitual life style, physical activity and dietary pattern during the eight weeks of study. Patients were excluded from the analysis if they consumed <85% of the packets or changed their medication or reported severe side effects.

2.3. Anthropometric and Biochemical Measurements

Anthropometric measurements including weight, height and waist circumference were measured at baseline and after 8 weeks. Weight was measured with a scale (Seca, Hamburg, Germany) while the subjects were minimally clothed without shoes. Height was measured with 0.5-cm accuracy, in a standing position without shoes, by using seca tape meter. Body mass index (BMI) was calculated as follow: weight/square of height (Kg/m²). Waist circumference of participants was measured using a tape meter in standing position [9]. Hip circumference was measured at the maximum bump hips. Waist to hip ratio (WHR) and waist-to-height ratio (WHtR) were calculated as follow: waist circumference/hip circumference and waist circumference/height. Blood pressure of the subjects was measured by standardized mercury sphygmomanometer after 15-min rest in sitting position and on the right arm. For each patient two measurements of blood pressure were taken. Venous blood samples were drawn after an overnight fast in baseline and at the end of experimental periods (Days 0 and 56) and were centrifuged at 4 °C and 500 g for 10 min to separate plasma. Fasting blood glucose (FBS) was measured by enzymatic colorimetric method using a glucose oxidation kit (pars Azmun Company, Tehran, Iran).

Insulin serum concentration was evaluated by using ELISA kits (mercodia Company, Uppsala, Sweden). HbA1c assessment kits were provided from Millan (Italy) company. The quantitative insulin sensitivity check index (QUICKI) was calculated by the inverse of the sum of the logarithms of the fasting insulin and fasting glucose: $1 / (\log (\text{fasting insulin } \mu\text{U/mL}) + \log (\text{fasting blood glucose mg/dL}))$ [10]. The homeostatic model assessment (HOMA) is a method used to quantify insulin resistance and beta-cell function. It was evaluated by this formula: $\text{fasting blood glucose (mmol/L)} \times \text{insulin concentration } (\mu\text{U/mL}) / 22.5$ [11]. It was considered HOMA- IR>5 as insulin resistance and HOMA- IR<3 as none insulin resistance [12].

2.4. Statistical Analysis

According to statistical methods for triglyceride variable [13], with confidence interval (CI) 95% and 80% power, the sample size with regard to possible loss of the samples was calculated among 20 patients in each group. The experimental data was analyzed by statistical package for the social sciences (SPSS software, version16; SPSS Inc., Chicago, IL, USA). The normality of the distribution of variables was determined by the Kolmogorov– Smirnov test. Analysis of covariance was used to identify any differences between two groups after intervention, adjusting for baseline measurements and covariates. The changes in anthropometric measurements, lipid profile and ox-LDL parameters of the participants between the beginning and end of the trial were compared by paired sample t-tests. The percent change for each variable was also calculated by formula $[(8\text{- weeks values} - \text{baseline values}) / \text{baseline values} \times 100]$. Also, p- value <0.05 was considered significant.

3. Results

Table 1. Baseline characteristics and biochemical values of diabetic patients in control and lentil sprout groups. ^a

	Control	Lentil sprouts
Age (year)	54±7.4	52±7.6
Women/men (n)	7/13	5/14
Duration of diabetes	7.4±6.6	11.7±19.2
Glucose lowering drugs (n)	13	19
Lipid lowering drugs (n)	2	9
Blood pressure lowering drugs (n)	3	7
Weight (kg)	78.5±10.5	78.3±9.8
BMI (kg/m ²)	28.2± 2.6	29.4±3.6
WC (cm)	98.9 ±8	97.9±7.7
WHR	0.8± 0.03	0.8±0.04
WHtR	0.6± 0.04	0.6±0.05
Insulin (mU/L)	8.9±4.4	8.1±5.3
HbA1c	7.4±1.2	8.3±1.3
HOMA-IR	3.4±1.7	3.2±2.1
QUICKI	0.32±0.02	0.34±0.04
FBS (mg/dl)	162±55	159±44

FBS, fasting blood glucose; BMI, body mass index; WC, waist circumference; WHR, weight- to- hip ratio; WHtR, weight- to- height ratio; HOMA-IR, (Hemeostasis model assessment)- Insulin resistance; QUICKI, (Quantitative insulin sensitivity check index)

Forty-eight subjects were enrolled and divided into two groups randomly, but only 39 were available for data analysis, because some of them could not complete the entire protocol or come for secondary evaluation. These 39 patients were included from 12 women and 27 men (Fig.1). No significant differences between the two groups were observed for mean age, duration of diabetes, weight, BMI, WC, WHR, WHtR, blood lowering pressure drugs; nor were there any significant differences between the pretreatment serum values of HbA1c, insulin concentration, FBS, HOMA and QUICKI between the two groups at baseline (Table 1). Subjects' demographics are shown in Table 1. There were significant differences in lipid lowering and Anti-diabetic drugs between two groups, therefore these variables were adjusted in the analysis. Eight-week biochemical values of the participants in two groups and treatment effect of LS on FBS, HbA1c, insulin concentration, QUICKI, HOMA, BMI, WC, WHR and WHtR are presented in table 2. Figure.2 presents the mean percent changes of variables in both groups after 8 weeks intervention. In the LS group the level of serum HbA1c significantly decreased compared with baseline but in the control group no significant change was seen. HOMA-IR and FBS tended to decrease in the LS group compared with baseline. The level of QUICKI increased compared with

baseline in the LS group. Patients in the intervention group did not report any side-effects for LS consumption.

^b calculated by using general linear model with 8-week values as dependent variables, baseline values as covariates and treatment group as a fix factor.

*Significantly different from baseline values (student paired t- test) P<0.05.

Figure 1. Flow chart of the study participants.

Figure 2. Mean differences of variables compared with baseline values in two groups (*significant difference within the groups using paired t-test, $p < 0.05$). FBS, fasting blood glucose; HbA1c, Glycated hemoglobin, Insulin; HOMA-IR, homeostasis model assessment- Insulin resistance; QUICKI, quantitative insulin sensitivity check index ; WC, waist circumference; WHR, waist to hip ratio; WHtR, waist- to- height- ratio ; BMI, body mass index .

4. Discussion

In the current study the effects of LS consumption on overweight and obese patients with type 2 diabetes were investigated. LS consumption in type 2 diabetic patients for 8 weeks had favorable effects on and glycemic control in overweight and obese patients with type 2 diabetes. Lentil sprouts consumption had not any adverse effects in the LS group. Increase in BMI > 25 resulted metabolic disorders especially between patients with metabolic syndrome or insulin resistance [14]. Vascuer et al showed in one meta-analysis study that WC, WHR and BMI were same in diabetes predicting [15]. Spieth et al reported that patients consumed low glycemic index (LGI) food, their BMI was lower than patients who consumed low fat diet [16]. Ludwig et al released that participants consumed LGI food had more satiety than people consumed high glycemic index (HGI) food, also intake LGI food decreased appetite and desire to receive food [17]. Some studies showed that HGI food consumption resulted weight increase in people [18,19]. In one study after LGI food consumption, without limitation in carbohydrate and low fat diet weight reduction was significant after 6 months [20]. In this study anthropometric indexes (WC, WHtR and BMI) tend to decrease in the LS group compared with baseline, but in the control group no reduction effects were seen (Fig.2). In one cohort study results reported that between patients experienced CVDs, more than other people, HbA1c was higher [21]. Jenkins et al found that HbA1c and FBS were significantly lower between patients with type 2 diabetes when they consumed LGI foods [22]. Results of some studies on non-communicable diseases showed that glycemic load (GL) and glycemic index (GI) of diet are independent risk factors for CVDs and type 2 diabetes [23]. HbA1c was lower in diabetic people when they consumed LGI and high fiber food compared with diabetic people when they consumed HGI and low fiber food [24]. HbA1c was lower in patients with type 2 diabetes than patients with type 2 diabetes when their diet has higher GI and GL [25]. 12-13 unit reduction in GI caused 39%-50% decrease in HbA1c [26]. In this study HbA1c

reduced in the LS group. 8% decrease in HbA1c in our study, in the LS group may be clinically valuable. Insulin resistance related to metabolic syndrome and type 2 diabetes [27]. In our study HOMA-IR reduced after 8 weeks LS consumption. Diet which is rich in fruits and vegetables due to plant fibers, carotenoids, anti-oxidants and phytosterols can prevent and control non-communicable diseases such as diabetes [28]. Herbal antioxidants had insulin-like effects and increased glucose absorption in peripheral tissues [29]. Lentils had a higher oxygen radical absorbing capacity (ORCA) value than most of the common fruits and vegetables such as apples, plums, blackberries, cherries, figs, peaches, pears, oranges, garlic, cabbage and almonds [30]. Increase in QUICKI level may be resulted from these components. The present study has a few limitations because the sample size was small and the study duration was 8 weeks.

5. Conclusion

Consumption of LS as supplementary treatment in type 2 diabetes could have favorable effects on HbA1c, FBS, QUICKI, and HOMA-IR. Further study with larger sample size and longer duration is required to confirm favorable effects lentil sprouts.
