Abstract: Design of a biogas plant supplying energy for the students' cafeteria while utilizing the abundant human waste has been done with an aim of significantly reducing wood consumption. Major fuels used in the cafeteria to prepare three meals per day for 3500 student's electricity, Naphtha, and fuel wood. Three years data have been examined to study the pattern of the energy demand, amounts, and price of the energy sources with emphasis on wood. Feed stock potentials, its compositions, nearness to the cafeteria, and various other criteria have been considered in the site selection. It has been found that technically possible to produce as much as 30 cu/m/day biogas in the selected site contributing to 44.5% reduction in wood consumption. Performance of digesters in the climate and weather condition of the region for similar feedstock has been assessed to determine the appropriate digester model. Chinese fixed dome and Deenbandhu models are common and have shown good performance. Detail design and dimensioning of the digester have been done. Financial feasibility has been evaluated using NPV (net present value), internal rate of return (IRR) and simple payback method. Positive NPV, 18.5% IRR and a payback period of 6.27 years have been calculated indicating the financial feasibility.

Keywords: Fixed Dome, Biogas, Digester, Retention Time

1. Introduction

Biogas technology is being used both at small scales and large scales in Ethiopia. Due emphasis has also been given for applications for rural people as means of reducing deforestation, improving indoor air pollution and reducing woman's time and effort in fuel collection. Applications in Hospitals, prisons and schools are also seen in major parts of the country. Plans also exist for wide spread use of the technology. For instance the Amhara prison administration has allocated significant budget for installation of biogas plants throughout the prisons in the region. [4] Application of biogas technology in Universities is very limited in the country. However research on biogas and production technologies are observed in some Universities. Currently there is no University who has applied biogas technology for use in reducing its fuel consumptions. The rising number of students and fuel cost and scarcity is forcing universities spent a lot to cook food three times a day for larger population. Additionally, due to commonly used traditional waste treatment technologies like septic tank permanent environmental solution is a must. The main research question emanates from these facts. How can

biogas plants contribute to reduced energy cost and eliminate environmental problems in universities while abundant feed stock.

Anaerobic digestion has been suggested as an alternative method of removing the high concentration organic waste. Several research groups have developed anaerobic digestion processes using different organic substrates [5-7]. The advantages of such processes over conventional aerobic processes are a low energy requirement for operation, a low initial investment cost and a low sludge production [8]. In addition, the anaerobic digestion process produces biogas, which can be used as a clean renewable energy source [9, 10]. In Europe, increasing numbers of biogas plants (BGPs) employing anaerobic digestion use food waste and manure as energy sources. Anaerobic digestions can be developed at different temperature ranges including mesophilic temperatures (approximately 35°C) and thermophilic temperatures ranging from 55°C to 60°C. Conventional anaerobic digestion is carried out at mesophilic temperatures, that is, 35–37°C. Several new processes have been reported for upgrading sludge digestion using thermophilic anaerobic digestion (55°C) and these represent an important alternative to mesophilic anaerobic digestion (35°C) [11, 12]. The thermophilic

temperature range is worth considering because it will lead to give faster reaction rates, higher gas production, and higher rates of the destruction of pathogens and weed seeds than the mesophilic temperature range. However, the thermophilic process is more sensitive to environmental changes than the mesophilic process. Two main technologies have been used for the rapid treatment of organic fraction of municipal solid wastes (OFMSW): sequential leach-bed anaerobic processes [13] and CSTR reactors [14] or Batch systems [15]. Both technologies have very simple designs and there are numerous reports on their use [16]. However, the CSTR systems are the least expensive solid waste digesters for simplest designs. It is superior and more economical than other competing technologies because it is grown in a similar anaerobic environment [17]. The system has high potential for application in developing countries [15].

Also, the large majority of industrial applications use one-stage systems and these are evenly split between “dry” systems (wastes are digested as received) and “wet” systems (wastes are slurried to about 12% total solids). However, the “dry” designs or high-solid [8] have proven reliable due to their higher biomass concentration, controlled feeding and spatial niches [18, 19]. Moreover, from a technical viewpoint, the “dry” systems are more robust and flexible than “wet” systems. Municipal solid waste (MSW) is a serious problem for urban communities. Organic solids are present in very large quantities as products or waste from agriculture, the food industry and market waste. Spain generates approximately 24 million tonnes of MSW annually. According to the data published by the National Plan of Urban Wastes (NPUR, 2000–2006), 40–45% of total MSW is the organic fraction of municipal solid waste (OFMSW). The composition of OFMSW is influenced by several factors, including regional differences, climate, collection frequency, season, cultural practices, as well as changes in composition [20]. At this respect, numerous papers have focused on aspects of anaerobic digestion biodegradation of the OFMSW according to its origin: e.g., market waste [21], fruit and vegetable [22], household waste [23], food waste [24], kitchen waste [25], biowaste [6] and organic fraction of municipal solid waste (OFMSW) [26]. In this regard an effort has been made design the anaerobic biodigester for the cafeteria.

2. Design Parameter

Following is a discussion of the most important parameters which must be considered in the design of an anaerobic digestion system:

i) Temperature - Three ranges exist for anaerobic digestion:

- Psychrophilic range - Between 5° and 25°C; characterized by slower methane production and longer retention times.

- Mesophilic range - Between 30° and 40°C; the most widely used of the three [27], this range balances heating costs with methane production.
- Thermophilic range – From 50° to 60°C; produces the most methane but is also the most sensitive, due to fewer bacterial species in existence.

Once a stable temperature is reached, fluctuations should be kept within 5°C to avoid killing the desired bacteria [28]. Thermophilic tolerance is generally less than that of lower temperatures [29]. Each temperature range at which the digester can be operated has its own advantages. The thermophilic process has been found to be superior to the mesophilic process from an energy balance and, thus, “profit” point of view [30]. Thermophilic digesters usually achieve better degradation of long-chain fatty acids, have a shorter retention time, and require less biomass compared to the quantity of methane produced. The thermophilic process also achieves higher pathogen and weed seed destruction than the mesophilic process alone [31]. However, the risk of ammonia inhibition is greater and more energy is required to operate a thermophilic digester. Thermophilic processes are considered to be more prone to instability than mesophilic due to fluctuations in input quality [32]. However, in a study of major centralized biogas plants in Denmark, Ahring [30] found no significant difference in volatile fatty acid concentrations between the two processes and conceded that the start-up time of thermophilic digesters is longer than that of a mesophilic reactor due to the low numbers of thermophilic bacteria in organic waste. Most of the agricultural digesters in the United States are mesophilic [33]. The process is slightly more stable and adaptable to fluctuations in feedstock quality than thermophilic. The lower heating requirements of mesophilic temperatures translate into lower costs. Residence time should be at least 15 days for adequate digestion [32].

Psychrophilic digesters require a solids retention time approximately twice as long as mesophilic. These digesters require the least amount of energy input. Biogas production is slow but gas quality and other parameters indicate favorable process stability [29]. These systems are commonly found in the form of a covered lagoon and, as such, they are usually subject to fluctuations in temperature.

ii) Loading Rate – This is expressed as the weight of volatile solids (VS) per unit of volume of digester capacity per unit of time. Loading rates typically range from 1.2 to 11.0 kg VS/m³/d for various types of digesters and manure sources [34]. While high loading rates use the digester volume more efficiently, they also increase solids concentration, retention time and alkalinity, which must be taken into consideration.

iii) Retention Time - The Hydraulic Retention Time (HRT) and Solids Retention Time (SRT) are the average lengths of time the liquid or solid portion of manure remains in the digester. Generally, the lower the operating temperature (e.g. psychrophilic digestion) the higher the retention time that is needed.

iv) Solids Concentration- Normally reported as the percentage dry matter and the volatile solid percentage of that dry matter, the solids concentration is necessary to determine the loading rate. The solids concentration also helps to determine the most suitable type of digester.

v) Alkalinity and pH - Optimum pH conditions for methanogenic bacteria range from 6.4 to 7.6 [29]. Other bacterial species are more tolerant to pH levels outside of this range.

3. Types of Biodigester

The reactor dimensions and biogas potential depends on:

- The type of substrates to be digested
- The quantity of each in metric tons per year
- The total solid content in percentage
- Total solids content (TS) = 100(%) - water content (%)
- The organic content in percentage: Organic dry matter content is determined by incinerating the dried sample at 550°C for six hours and weighing the remaining ashes.
- *Organic content (ODM)* = $\frac{\text{mass of TS(g)} - \text{mass of ashes (g)}}{\text{mass of TS(g)}} \times 100$
- The size of the digester (Vd) is determined by the retention time (RT) and the daily substrate input in m³ (Sd).
- The following formula can be used in order to calculate the appropriate volume:

$$V_d = S_d \times RT$$

Several different systems have been designed for anaerobic digestion. Following are basic descriptions of the more popular systems used on farms.

3.1. Plug Flow System

The plug flow system usually takes the form of a long concrete tank with a slight grade over the length. Influent is either continuously or intermittently added to one end and flows by gravity to the opposite end. The contents are not mixed mechanically. The retention time is thus a function of channel length, channel grade, and the loading rate. The plug flow digester is best suited for manure with a higher solids content (11 to 13% total solids) such as that of a dairy operation [35]. Figure 4 shows the main elements of a plug flow digester system.

3.2. Complete Mixed System

Also known as a Completely Stirred Tank Reactor (CSTR), the complete mixed system is most commonly a circular tank with a mechanical agitator. The mixing prevents settling and maintains contact between bacteria and the manure. It also helps maintain a uniform temperature [37]. Electricity input costs are higher due to the intermittent mixing of the digester. However, the mixing can cause foaming in the tank, which is undesirable because it occupies digester volume and can clog gas lines. Complete mix systems are able to handle the widest range

of solids concentrations (3 to 10% total solids) [35]. Influent is often added to the digester as effluent is excreted in small quantities at regular intervals. Therefore the retention period of manure in a complete mix digester is not necessarily uniform.

Fig 1. Typical plug flow digester system [36]

Fig 2. Fixed Dome Biogas Digester [36]

4. Digester Design

4.1. Digester Selection

Common digester types in developing countries are fixed dome and floating drum plants. Fixed dome plants are made entirely below the ground saving space and being less affected by damage and daily temperature fluctuations. They are the most commonly built digester in the hot climate of the region. In floating drum plants the gas holder is made of stainless steel which contributes to the expensiveness of the digester but its operation is easy to understand than fixed dome plants since the gas holder is above the ground. Among fixed dome types Deenbadhu and Chinese fixed dome represent the most built and well performing digesters in the region. For instance digesters in Felegehiwot Hospital (65cu.m digester) and Bahir Dar Prison (100cu.m digester) have Deenbadhu type fixed dome plants which are serving a lot. [4] Biogas digester is Addis Zemen (a small city near Bahir-dar) prison has a well operational fixed dome digester.

4.2. Sizing of Digester

a) Active slurry volume (Vs)

For normal retention time of HRT=40 days [1] and waste amount of W=400kg/day,

$$V_s = 2 \times \text{HRT} \times W / 1000 \text{ cu.m}$$

$$V_s = 32 \text{ cu.m}$$

b) Gas production G

Specific gas yield of human waste $G_s=0.03\text{cu.m/kg}$ [1]
and total amount of waste for

1000 people with 0.4kg/person/day [1] is,

$$G=1000*0.4*0.03=30\text{cu.m/day}$$

c) Water volume

5lit cans are used during toilet cleaning and 0.75lit cans are used for flushing after use.

Hence the total volume of water is,
 $0.75\text{lit/person}*1000+5\text{lit/toilet}*30\text{ toilet}=900\text{lit}$

For retention time of 40 days water volume is 36cu.m

Total digester volume $32+30+36=98\text{cu.m}$

Shown in table 1 are the dimensions of 100cu.m biogas plant as determined by Selam technical and vocational Center (STVC); contractors on biogas plants. The dimensions refer to digester design shown on figure 2.

Table 2 shows the bill of quantities as specified by STVC [38] and price of quantities as determined by market Survey during October 2008

Fig 3. General biogas plant designs [39]

Table 1. Dimensions of 100cu.m fixed dome plant

Components	Symbol	Dimensions (cm)
Length of outlet	A	1150
Breadth of outlet	B	200
Height of outlet	D	100
Radius of pit	C	425
Radius of digester	F	365
Height of digester wall	H	310
Depth of pit (excavation)	E	400
Height of dome	I-H	30
Height of outlet passage	I	340
Thickness of concrete dome		60
Expansion canal		Length=22.5m, depth=50cm

Cost benefit analysis has been done using net present value (NPV) pay back times and internal rate of return.

$$NPV = R \times \frac{1 - (1+i)^{-n}}{i} - \text{Initial Investment}$$

The benefits are calculated based on replacement ratio of biogas and commonly used Eucalyptus wood. It has been suggested that 1cu.m biogas replaces 1.3kg fire wood [1]. Amount of fire wood replaced,

$$30*1.3=39\text{kg wood/day}$$

Market survey indicates 20kg wood costs 30birr giving a ratio of 1.5birr/kg wood.

Monthly saving is then,

$$39\text{kg/day}*1.5\text{birr/kg}*30\text{days}=1755\text{birr/month}$$

Assuming 30cu.m/day gas is available for 10 months a year due to lower gas production during rainy season, Annual saving is $17,550\text{birr}$ [2].

In 2008/2009 the faculty spent $39,424.76\text{birr}$. Hence this saving represent a reduction of 44.5% cost due to wood considering electricity irregularity at the time. The useful life time of a biogas plant is up to 40 years but the economic life time is 20 years since the value of benefit discounted to present time for time after 20 years is negligible. The discount rate has been taken to be the bank interest rate of 4% . Other maintenance costs include cleaning of the digester every four years which is typical time based on experience on homogenous human waste digesters. Based on current lorry costs $1,000\text{birr}$ is required for cleaning.

Table 2. Bill of quantities and cost estimation

Description	Unit	Quantity	Unit price Birr/unit	Total cost birr	Transport cost birr
Block	Pcs	1446	5	7,230	2,000
Cement	Quintal	68	300	20,400	1,500
Sand	Cu.m	30	185.71	5950	800
Stone	Cu.m	72	52	3744	2,000
Gravel	Cu.m	7	230	1610	400
Rc bar 10	Pcs	33	152	5016	200
Engine oil	Lit	8	25	200	

Wax	Kg	4	40	160
Gas pipe	m	250	30	7,500
Slurry collector pipe	m	130	30	3,900
Stoves	no	4	600	2,400
Various fitting s	Pcs	22		889
Masonry	Days	50	450	22,500
Labor	Days	5	30/person/day	9,000
Supervision	Days	15	375	5,625
Excavation	Days	10(10 people)	30/person/day	3,000
Total				110,000birr

Payback time N (yrs), $N = 110,000/17,550$, $N=6.27$ years
NPV calculation shows a value of 129,915 and internal rate of return 18.5%

Larger and positive NPV and the IRR value indicate financial viabilities of the proposed project.

5. Conclusions

It has been found that installation of biogas plant leads to larger savings besides environmental and sanitation benefits. The gas thus produced replaced 44.5% of the cost due to wood. The economics of the system as evaluated by reliable Net present worth method proves a large and positive value indicating the attractiveness of the investment. This implies successful installation of this plant and similar others will prove to be economical in the face of rising number of students and fire wood scarcity and prices. Environmental values are immense as a waste from 4 blocks having 1000 people has been treated efficiently as compared to septic tanks and direct disposal. This contributes a lot in environmental protection and sanitation efficiency. Also the gas produced replaces significant amount of wood contributing to reduced deforestation. If similar projects are installed in all universities, its impact on the forest protection will be well vivid. The bio fertilizer thus produced can be used for plantations and gardens found in the faculty. This has dual benefit in the sludge management and bio-fertilizer utilization. It can further open a window of opportunity in introducing bio-fertilizer for the local famers around Bahirdar.

Installation of the plant is highly recommended due to its financial and environmental benefits. Similar applications in other Universities contribute a lot in realizing its economical benefits. It leads to forest savings, energy self dependency and efficient resource utilization. The university can be a model in renewable energy and energy self sufficiency if more efforts are made to exploit the abundant resources (including cafeteria waste) and the warm climate of Bahir-dar which creates favorable condition for microbial processes.
