Abstract: Background: Malaria is one of the most important infectious inflammatory diseases worldwide which affects vital organs including gastrointestinal and kidneys. Higher prevalence of malaria related renal failure, current malaria drugs nephrotoxicity and drug resistance to malaria calls for continued research in anti-parasitic as well as anti-disease inflammatory pharmaceuticals. Asiatic acid, a plant phytochemical extract, has antioxidant, pro-oxidant and diuretic properties. Here we report influence of Asiatic acid-pectin hydrogel matrix patch application in *P. berghei*-infected Sprague Dawley rats on renal function and electrolyte handling. Materials and Methods: Asiatic acid (5mg/kg)-pectin patch was applied on the dorsal neck region of the rat on day 7 post infection and monitored for parasitaemia, and physicochemical changes. Urine and blood were collected for measuring various biochemical parameters to estimate renal function and electrolyte handling. Results: Asiatic acid-pectin patch application had significant influence on food and water intake as well as weight changes, urine electrolytes, glomerular filtration rate, and antioxidant markers together with hormonal changes of aldosterone and vasopressin. Conclusion: Application of the once-off Asiatic acid (5mg/kg)-pectin patch influence renal function and renal electrolyte handling while ameliorating, biochemical and hormonal derangements induced by malaria. Novelty of the Work Here we show for the first time a) the efficacy of Asiatic acid (AA) in suppressing murine malaria by way of administering the phytochemical using the amidated pectin hydrogel matrix patch transdermal drug delivery system, b) diminution of asiatic acid dose applied from 10mg/kg oral to 5mg/kg by transdermal, c) reduction of time once-off patch application from five days to three days, d) attenuation of oxidative and hormonal derangements in malaria and e) the amelioration of renal function together with improvement in renal electrolyte handling. The results may be of benefit in patient care replacing the multiple dosing approaches used in malaria management.

Keywords: Asiatic Acid, Malaria, Transdermal Drug Delivery, *Plasmodium berghei*, Sprague Dawley Rats, Renal Failure

1. Introduction

Malaria has remained one of the most recalcitrant disease with its varied sequelae that imamate from the bite of the anopheles mosquito during its feeding on infected human blood meal when the *Plasmodium* parasite is transmitted to human hosts. The parasite is an obligate intracellular protozoa invading several body systems and organs during

the infection. Different developmental stages of the parasite has been demonstrated to be present in the intravascular compartment (red blood cells-RBC's), hepatocytes, gastrointestinal cells, the renal system and the brain tissue which are invaded causing different degrees of damage in each organ [1]. Gut and hepatic invasion by the parasite leads to inflammatory gut and hepatic syndromes. Consequently, malaria present a number of fatalistic syndromes dependant

on the organ system mostly affected although the symptomatic expression of the disease is mainly associated with the blood stage of the parasites. The malarial triad include fever, anaemia, and splenomegaly. However, gastrointestinal symptoms, such as abdominal pain, diarrhoea, and vomiting, develop in patients with falciparum malaria [39, 40]. Small intestine pathological changes of tongue-shaped jejunum and duodenum villi [34], width extended and shortened villi [13], villi rupture and bleeding contribute to gastrointestinal malfunction [6, 45, 48] leading to fluid loss in malaria compromising renal function. Moreover, the anorexic phenotype which causes malnutrition and the associated fluid losses through increased intestinal permeability in malarial [49] leads to several changes that affect and dysregulate the gut-brain axis leading to dehydration, hypovolaemia, renal insufficiency, cachexia and death. The intestinal bleeding induced may hypovolaemia and bleeding may lead to an oxidative propensity through release of free haemoglobin and high grade inflammation by way of immune system activation with resultant renal electrolyte handling dysregulation, acute kidney injury and renal dysfunction amongst other derangements [2].

In malaria, acute renal failure (ARF) may develop without warning when the disease is not properly managed. Malaria ARF (MARF) may develop into malaria chronic renal failure (MCRF) or the later might develop independently without an acute phase [17]. In non-immune adults and children MARF is one of the leading causes of ARF in Africa South of the Sahara [32]. Mortality from MARF has been rated at 14-45% [3]. Aetiology of MARF depends on the immunological and inflammatory host responses [37], microcirculation blockage by non-parasitized red blood (npRBC's) cells and parasitized red blood cells [pRBC's] [11, 25], hypovolaemia from peripheral blood pooling and ischaemic acute tubular necrosis [ATN] [33]. Treatment, therefore should be aimed at avoiding ARF development or reversing the renal pathophysiology where it has occurred.

Current malaria treatment regimens have a number of setbacks. Amongst these, use of 4- or 8-aminoquinolone drugs in malaria has been associated with increased sodium wasting and hyperkalaemia [31]. Artemisinin and its derivatives, current drugs of choice in malaria treatment, rapidly clear parasitaemia but create reactive oxygen species (ROS) leading to red blood cells (RBC's) damage with post artemisinin treatment induced drug haemolysis (PADH) and ARF [16, 38, 42]. Moreover, multi-drug resistance has emerged in antimalarial treatment regimens. This introduces one of the most prominent obstacle in the fight against malaria. Therefore, continuing antimalarial research is paramount especially one that is aimed at amelioration of malaria pathophysiology like MARF.

Plant extracts including phytochemicals open up an avenue worth exploring as anti-parasitaemia as well as malaria renal pathophysiology (anti-disease) alexia. Per oral administration of Asiatic acid (AA) has been demonstrated to have both anti-parasitic as well as anti-disease influence in malarial complications. This followed pre-infection administration of

AA (chemoprophylaxis) and post-infection administration of the phytochemical in *Plasmodium berghei*-infected male Sprague Dawley rats [20]. Also worth noting in these studies is the observation that AA (10mg/kg, as an oral concoction, was able to suppress parasitaemia in *Plasmodium berghei*-infected Sprague Dawley rats as well as amelioration of severe malarial anaemia [22]. Furthermore, an even lower dose of AA as an AA (5mg/kg)-amidated pectin hydrogel patch was shown to suppress parasitaemia as well as to ameliorate severe malarial anaemia (SMA) in a post-infection treatment experimentation [23]. Not only does this approach increase the number of potential antimalarial therapies, but it also introduces a possible pathophysiology-directed approach for both malaria prevention and treatment.

Asiatic acid is both an antioxidant (hydrogen bond acceptor- BDA) and a pro-oxidant (hydrogen-bond donor- HBD) capable of redox-reactions participation [36] with a potential to eradicate the parasite while ameliorating untoward malaria disease sequelae. AA is pleiotropic in nature [12, 50, 51] with its diuretic effect [35] and non-nephrotoxicity [52] makes it more amenable in the management of MARF. However, the influence of AA in the management of MARF has not been reported. Interestingly, it makes sense that therapeutics with anti-inflammatory targets in malaria have a higher success chance in eradicating the parasite as well as forestalling MARF development.

Renal dysfunction in malaria is commonly associated with electrolytes mismanagement by the nephron accompanied by arginine vasopressin (AVP) and aldosterone (ALD) aberrations before overt disease signs and symptoms are apparent [30, 31] through increased oxidative stress from oxygen free radicals and ONOO⁻ [7, 18]. The hormonal and electrolyte abnormalities formulate the renal disease aspects of malaria, as contrasted to parasitic infection, which need to be managed concurrently with parasitaemia reduction strategies. Hypovolaemia of malaria, through red blood cell (RBC's) haemolysis and reduced water and food intake, increases both AVP and ALD. Therefore, investigation of MARF will, of necessity, involve demonstration of both AVP and ALD activities together with changes in electrolyte concentrations in both plasma and urine. The influence of AA administration on AVP and ALD in malaria, renal function or any other disease is not yet reported. Also still a grey area exists to AA's antioxidant and anti-inflammatory capacities in malarial electrolyte handling.

Studies have indicated that the mode of drug delivery, e. g. transdermal drug delivery system (TDDS) compared to oral administration, plays a crucial role in the ultimate efficacies of the drug to the extent of salvaging antimalarial potency of chloroquine [26, 28]. As a result to further enhance the efficacy and reduce the dosage of AA in malaria management, an AA-amidated pectin hydrogel matrix patch, commonly referred to as "the patch" was mooted as a novel method of phytochemical drug delivery and antimalarial therapy. Indeed, transdermal delivery of AA has been reported to result in the reduction of the dose administered and in suppressing parasitaemia [23]. We hypothesised that

the antioxidant capacity of AA may influence electrolyte transporters by reducing oxidative stress, which is common in malaria infection, and thus play a crucial anti-inflammatory role in malaria pathology.

Therefore, as a follow up, the aim of this study was to investigate the influence of AA-TDDS on malarial progression, malaria nutritional status, malaria antioxidant capacity, host renal function and renal electrolyte handling in male Sprague Dawley rats as a novel approach in both AA administration and AA malaria treatment.

2. Materials and Methods

2.1. Materials

2.1.1. Drugs, Chemical and Accessories

Asiatic acid (AA >97% purity), Giemsa stain, dimethyl sulphoxide (DMSO), chloroquine diphosphate were purchased from Sigma-Aldrich (St. Louis, Missouri, USA). All other chemicals and reagents used were obtained from reputable suppliers and were of analytical grade.

2.1.2. Animals

Male Sprague-Dawley (SD) rats weighing 90-120 g (6 weeks old) were obtained from Biomedical Research Unit (BRU), of the University of KwaZulu-Natal (UKZN) where they were bred and housed for the entire experimental period. The animals were kept under maintained laboratory conditions of constant temperature ($22\pm1^{\circ}\text{C}$); CO_2 (<5000 ppm), humidity of $55\pm5\%$ and illumination (12 h light/dark cycles). The animals had full access to food, standard rat chow (Meadows Feeds, Pietermaritzburg, South Africa) and water *ad libitum*. Infected non-treated control (IC) animals were euthanatized on day 12 post infection. All other animal groups were euthanatized sacrificed by day 21. Lethal inhalation anaesthesia with isoform (Safeline Pharmaceuticals, Rooderport, South Africa) for 3 minutes via a gas anaesthetic chamber (100 mg/kg) was used to overdose euthanize all the animals. All experiments and protocols used in this study were reviewed and approved by the animal ethics committee of the UKZN with ethical clearance numbers 079/14/Animal and 013/15/Animal issued.

2.1.3. Malaria Parasites

Chloroquine-susceptible strain of *Plasmodium berghei* ANKA, was a kind donation from Professor Peter Smith (University of Cape Town, Division of Clinical Pharmacology, South Africa). *P. berghei* (10^5 parasitized red blood cells [pRBC's] suspension in saline) was inoculated intraperitoneal (ip) [9] into stock animals which were euthanatized after 12 days and the infected blood was harvested, washed and stored at -80°C in freezing media (30% glycerol in phosphate buffer) until used.

2.1.4. Experimental Design

The study was a 21 day protocol of animals groups ($n=6$ per group) administered either with AA-pectin matrix patch or chloroquine-pectin patch post-infection with *P. berghei*.

The groups were as follows:

- i) Non-infected treated control DMSO plus AA5 (NIC)
- ii) Infected non-treated control (IC)
- iii) Infected groups treated with CHQ 30mg/kg patch (30CHQ)
- iv) Infected groups treated with AA 5mg/kg patch (AA5)
- v) Non-infected administered DMSO patch absolute control (AC)

Preliminary findings have shown that AA 5mg/kg had the highest efficacy and it will be the only dose reported here unless where it is applicable to stress a point. The AC and NIC groups did not show any difference. As a result only the NIC results are reported.

2.2. Methods

2.2.1. Induction of Parasitaemia

Chloroquine-susceptible strain of *P. berghei* ANKA (10^5 pRBC's suspension in saline) was inoculated intraperitoneal [9] in the positive and test animals. Non infected Control Animals (NIC): Equal volume of saline was administered to the control animals.

2.2.2. Influence of AA on Sub-Chronic Studies

Experiments were conducted over a period of 21 days to establish the influence of AA on renal function and electrolyte handling in murine-malaria affected SD rats. Animals per group ($n = 6$ per group) were housed individually in Makrolon polycarbonate metabolic cages (Techniplast, Labotec, South Africa) with food and water availed *ad libitum*.

2.2.3. Preparation of AA-Pectin and CHQ Hydrogel Patches

Amidated pectin hydrogel matrix patches were prepared using a previously described protocol by Musabayane *et al.*, (2003) with slight modifications [27]. Low methoxyl amidated pectin with a degree of esterification (DE) of 23% and an amidation of 24% was used for the preparation of the AA and CHQ patches. AA (5mg/kg) or CHQ (30mg/kg) were added to amidated low methoxyl pectin (4.4g) and dissolved in deionized water (110mL) in separate beakers. The concoctions were agitated at 37°C in a water bath at a speed of 38 x G using an electric motor mixing rotor (Heidolph instruments GmbH & Co. KG, Schwabach, Germany) for 15 minutes. Subsequently, DMSO (2mL), 1.65mL eucalyptus oil (Barrs Pharmaceutical Industries, Cape Town, South Africa) and 1.65mL vitamin E (Pharmacare Ltd, Johannesburg, South Africa) were added to the mixtures and mixed for 1h 30 minutes. Aliquots (11 mL) were transferred to petri dishes with a known diameter and frozen at -4°C for 18 hours following which 2% CaCl_2 solution was added on top of the frozen pectin and left to stand at room temperature ($\pm 25^{\circ}\text{C}$) for 10 minutes to allow for cross-linking and formation of the matrix patch. The patches were then stored in a refrigerator at 4°C until use.

2.2.4. Application of the Patch

Three discs ($4\pm 1\text{mm}^2$) were punched out from AA

(5mg/kg) patch or CHQ (30mg/kg) and applied once-off onto the shaved dorsal region of the animal from Day 7 to Day 10 (three days). The jacket holding the patch in place was made from clinically sterile adhesive fabric plaster (Medioplast, Neomedic, Rickmansworth, and Herefordshire, UK) which caused no discomfort to the animals. Notes on patch application: The dorsal neck region was selected because it was the least accessible to the animals' grooming habits and avoided removal of the patch by the animals. The transdermal delivery (TTD) system aimed at reducing phytochemical amount delivered to the animal, dosing frequency, treatment duration and general animal discomfort. A theoretical total AA yield of the patch was estimated at 1µg/per disc for 5mg/kg AA dose and 3µg was administered as three discs were applied per animal to provide equivalent of five day treatment.

2.2.5. AA5-Pectin Patch Influence on Parasitaemia Monitoring

Parasitaemia% monitored 72 hours post inoculation (pre-patent period), every third day up to day 7 [patent period] [4], every day during patent/treatment period of five days and thereafter every other day (post-treatment period) until day 21. A 15-20% parasitaemia on day 7, confirmed by Giemsa staining under a microscope (Olympus Cooperation, Tokyo, Japan) [20], was considered as stable state malaria where administration of AA and treatment with 30CHQ was commenced

2.2.6. AA5-Pectin Patch Influence on Physicochemical Monitoring

Body weights, food and water intake were monitored gravimetrically using a balance Mettler balance PC 180-instruments (Protea Laboratory Services, Johannesburg, South Africa) in control and treated animals at 09h00 every 3rd day during the pre-treatment, treatment and post treatment periods.

2.2.7. Plasma and Tissue Sample Harvesting

All animals were euthanatized by exposing to isofor (Safeline Pharmaceuticals, Roodeport, South Africa) for 3 minutes via a gas anaesthetic chamber (100 mg/kg). Blood samples were collected by cardiac puncture into pre-cooled lithium heparin tubes onto melting ice. Blood in heparin tubes was immediately centrifuged for 15 minutes at 959 x G in a 4°C centrifuge (Eppendorf International, Hamburg, Germany) and plasma separated. The liver, kidney, muscle and heart were removed, snap frozen in liquid nitrogen and stored together with the plasma in a Bio Ultra freezer (Snijders Scientific, Tilburg, Netherlands) at -80°C until use. Protein content of all organs was quantified using the Lowry method and samples standardized to one concentration (1 mg/mL).

2.2.8. AA5-Pectin Patch Influence on Urinalysis

Urine was collected over a 24 hour period in metabolic cages every third day during the pre-patent, patent/treatment and post treatment periods to investigate influence of AA on urine parameters. Gravimetric method was used to determine

urine volume. Quantitative measurements of total urinary outputs and plasma concentrations of Na⁺, K⁺, Cl⁻, urea and creatinine were performed using Beckman Coulter (Synchron CX3 Clinical Systems, Fullerton, California, USA) with reagent kits from Beckman Coulter (Dublin, Ireland). Creatinine concentrations used to calculate the glomerular filtration rate (GFR) using formulae: $GFR = ([U_{creat}] \times UV) / ([P_{creat}] \times 1440 \text{ minutes})$ where U_{creat} is urine creatinine concentration, P_{creat} is plasma creatinine concentration and UV is 24 hour urine volume. Renal clearance (C) and fractional excretions (FE) were calculated with the standard formulae $C = U \times V/P$ and $FE = C/GFR$ where U is the urinary concentration, V is the urine flow rate and P is plasma concentration as used by Salman et al [43]. AA5-pectin patch influence on haemolysis: To corroborate both haematological aberrations in malaria and hypoxia-induced tissue damage, plasma enzymatic activity of lactate dehydrogenase (LDH) was estimated. LDH activity is related to haemolysis extent, renal tissue damage or renal disease as well hyperlactaemia. Enzymatic changes underscore its release from tissues in necrosis or increased synthesis. LDH was determined in plasma using the Architect c8000 Abbott Diagnostic Clinical Chemistry Analyser (Abbott Laboratories, Illinois, USA).

2.2.9. AA5-Pectin patch Influence Aldosterone (ALD) and Arginine Vasopressin (AVP)

Levels of ALD and AVP are affected in malaria and were estimated to show the influence of AA administration on renal electrolyte handling. Malaria increases levels of both hormones through sodium wasting and volume depletion for ALD and AVP, respectively. Blood samples collected from treated and untreated groups of SD rats were used in ELISA methods hormonal estimates. ALD estimations: An Elabscience ALD (Aldosterone) ELISA kit Catalog No, E-EL-0070 (Elabscience Biotechnology Co. Ltd., WuHan, P. R. C.) was used to measure the hormone concentration following manufacturer's instructions. The detection limit was 15.63-1000pg/mL with a sensitivity of 9.38pg/mL. AVP estimations: An Elabscience Rat ADH (Antidiuretic Hormone) ELISA kit Catalog No, E-EL-0552 (Elabscience Biotechnology Co. Ltd., WuHan, P. R. C.) was used to measure the hormone concentration following manufacturer's instructions. The detection limit was 31.25-2000pg/mL with a sensitivity of 18.75pg/mL.

2.2.10. Influence of AA on Oxidative Stress (OS) in Malaria

OS infringes upon normal electrolytes handling in the proximal and distal convoluted tubules. The activities of superoxide dismutase (SOD), glutathione peroxidase (GPx) and levels of malonyl aldehyde (MDA) were measured in kidney tissues to estimate influence of AA on OS. SOD activity estimation: Tissue SOD activities of kidney homogenates from NIC, AA treated and IC SD rats were assessed by measuring the dismutation of superoxide radicals generated by xanthine oxidase and hypoxanthine in a convenient 96 well format using a commercially available from abcam Superoxide Dismutase Activity Assay kit

(colorimetric) catalogue no. ab65354 (abcam, Canada) according to the manufacturer's instructions. GPx activity estimation: Activity of GPx was determined in AA-pectin patch applied and control animals' kidney tissues using abcam Glutathione Peroxidase Activity Assay kit (colorimetric) catalogue no. ab102530 (abcam, Canada) according to the manufacturer's instructions. MDA concentration estimation: MDA levels in kidney tissues from NIC, IC and infected-AA treated animals were estimated using a previously described method [14] with some modifications.

2.3. Statistical Analysis

Data are presented as the means $\pm$ standard error of mean (SEM). Overall statistical comparisons between the control means and experimental groups were performed with GraphPad InStat Software (version 5.00, GraphPad Prism

software (San Diego, California, USA), using one-way analysis of variance (ANOVA), followed by Tukey-Kramer post hoc multiple comparison test. A value of $p < 0.05$ was considered significant.

3. Results

3.1. Influence of AA5-Pectin Patch on % Parasitaemia

The degree of % parasitaemia decrease indicated the efficacy treatment on malaria. A comparisons of % parasitaemia during the sub-chronic study was made between AA5-pectin applied animals and controls (Table 1). AA5-TDDS administration had lower % parasitaemia at days 7-12 compared to IC and CHQ treatment ($p < 0.05$, respectively) and at day 21 compared to CHQ treatment.

Table 1. % Parasitaemia comparisons between AA5-TDDS (AA 5mg/kg transdermal drug delivery system) application and controls. Values are presented as means $\pm$ SEM ($n = 6$ per group). *, # $p < 0.05$ compared to the IC (infected not treated control) and 30CHQ patch, respectively.

Protocol	Parameter	Sub-chronic Study Time-Course		
		Pre-patent (D3) % Parasitaemia	Patent/Treatment (D7-10) % Parasitaemia	Post-treatment (D21) % Parasitaemia
Post- infection Asiatic acid Transdermal Drug Delivery	IC	3.5 $\pm$ 0.2	13.00-69.33 $\pm$ 8.6	N/A
	30CHQ	2.17 $\pm$ 0.3	10.33-43.33 $\pm$ 11.5	0.3 $\pm$ 0.23
	AA5-TDDS	3.23 $\pm$ 0.4	17.42-27.68 $\pm$ 5.7*#	0.00#

3.2. Influence of AA5-Pectin Patch on Physicochemical Changes

Eating and drinking habits indicated the bio-physiochemical status of both infected and non-infected animals. Comparison of food and water intake together with % weight gain was made between AA5-pectin and controls (Table 2). Physiochemical properties were significantly preserved by AA5-pectin patch compared to the IC, and CHQ ($p < 0.05$, respectively).

Table 2. AA5-TDDS (AA 5mg/kg transdermal drug delivery system) influence on % weight changes, food and water intake. Compared to controls values are represented as means $\pm$ SEM. *, # $p < 0.05$ compared to the NIC (non-infected control), IC (infected not treated control) and CHQ (30mg/kg chloroquine), respectively.

Parameter	Protocol		Pre-patent (D 3)	Patent/Treatment (D7-10)	Post-treatment (D 21)
A. Food intake (g/100g)	Post- infection AA TDD treated	NIC	11 $\pm$ 1	10 $\pm$ 2	12 $\pm$ 2
		IC	11 $\pm$ 1	6 $\pm$ 4	N/A
		30CHQ patch	11 $\pm$ 2	9 $\pm$ 1	8 $\pm$ 1
		AA5-TDDS	11 $\pm$ 1	10 $\pm$ 2*#	12 $\pm$ 2#
B. Water intake (mL/100g)	Post- infection AA TDD treated	NIC	15 $\pm$ 1	13 $\pm$ 2	15 $\pm$ 2
		IC	14 $\pm$ 1	7 $\pm$ 2	N/A
		30CHQ patch	15 $\pm$ 1	13 $\pm$ 1	14 $\pm$ 3
		AA5-TDDS	15 $\pm$ 1	15 $\pm$ 2*#	15 $\pm$ 2#
C. % body weight change	Post- infection AA TDD treated	NIC	8 $\pm$ 1	12 $\pm$ 1	14 $\pm$ 1
		IC	8 $\pm$ 4	-4 $\pm$ 2	N/A
		30CHQ patch	8 $\pm$ 1	10 $\pm$ 1	12 $\pm$ 1
		AA5-TDDS	8 $\pm$ 1	11 $\pm$ 1*#	15 $\pm$ 1#

3.3. Influence of AA5-Pectin Patch on Lactate Dehydrogenase (LDH) Activity

The degree of haemolysis was reflected by the activity of LDH in plasma. The influence of AA5-pectin hydrogel matrix patch on LDH activity was compared (Table 3). Application of the AA5-pectin patch decreased LDH activity significantly on day 12 as compared to either IC or 30CHQ patch ($p < 0.05$, respectively).

Table 3. Influence of AA5-TDDS (AA 5mg/kg transdermal drug delivery system) on lactate dehydrogenase activity compared to controls. Results presented as mean $\pm$ SEM ($n = 6$ in each group). *, # $p < 0.05$ compared to IC (infected not treated control) and 30CHQ (30mg/kg chloroquine) -pectin patch, respectively.

Parameter	Transdermal Delivery Post Treatment Day 12 LDH (U/L)
NIC	551.00 $\pm$ 42.29
IC	2453.00 $\pm$ 235.20
CHQ 30mg/kg Patch	1063.00 $\pm$ 51.85
AA 5mg/kg Patch	598.00 $\pm$ 46.59*#

3.4. Influence of AA5-Pectin Patch on Glomerular Filtration Rate [GFR]

Changes of GFR overtime reflected the status of renal function in the NIC, IC and treated animals (Figure 1). Once-off AA-pectin patch influence on GFR compared to NIC, IC and 30CHQ. AA5-TDDS application preserved GFR compared to IC and 30-patch treatment ($p < 0.05$, respectively) at pertinent time periods.

Figure 1. Comparison of GFR (Glomerular filtration rate) changes in AA5-TDDS (AA 5mg/kg transdermal drug delivery system) and controls. Values are presented as means and vertical bars indicate SEM ($n = 6$ per group). *, # $p < 0.05$ compared to IC (infected not treated control), NIC (non-infected control), 30CHQ (30mg/kg chloroquine) pectin matrix patch, respectively.

3.5. Influence of AA5-Pectin Patch on Urine Na^+ Output (Mmol/L/Day)

Figure 2. Urine Na^+ of AA5-TDDS (AA 5mg/kg transdermal drug delivery system) applied animals compared to controls. Results presented as mean $\pm$ SEM ($n = 6$ in each group). *, # $p < 0.05$ compared to IC (infected not treated control), 30CHQ (30mg/kg chloroquine)-pectin patch, respectively.

Renal Na^+ preservation was shown by the amount of Na^+ in the urine. Comparison of urine Na^+ output in AA5-pectin patch applied animals and controls showed (Figure 2). AA5 patch to significantly preserved Na^+ excretion compared to IC and 30CHQ patch ($p < 0.05$, respectively) at all relevant times. Influence of AA5-pectin patch on K^+ output

(mmol/L/day): Renal handling of K^+ was shown by the urine K^+ activity, and urine K^+ output in AA5-pectin patch applied animals and controls (Figure 3). AA5 patch significantly preserved K^+ excretion compared to IC and 30CHQ patch ($p < 0.05$, respectively) at all relevant times

Figure 3. Urine K^+ output for AA5-TDDS (AA 5mg/kg transdermal drug delivery system) compared to controls. Values are presented as means and vertical bars indicate SEM ($n = 6$ per group). *, # $p < 0.05$ compared to IC (infected not treated control), 30CHQ (30mg/kg chloroquine), respectively.

3.6. Influence of AA5-Pectin Patch on Urine Cl^- Output (Mmol/L/Day)

Urine Cl^- output in AA5-pectin patch applied animals and controls (Figure 5). AA5 patch reduced Cl^- excretion compared to IC and 30CHQ patch ($p < 0.05$, respectively) at all relevant times. Influence of AA5-pectin patch on absolute Na^+ excretion ($\mu\text{mol/mL/min}$): The influence of AA5-pectin patch on absolute Na^+ excretion and the controls were compared (Figure 6). Absolute Na^+ excretion was significantly lower in the AA5-pectin matrix patch administered infected animals compared to the IC and the 30CHQ-pectin matrix patch treated groups ($p < 0.05$, respectively).

Figure 4. Urine Cl^- output of AA5-TDDS (AA 5mg/kg transdermal drug delivery system) compared to controls. Results presented as mean $\pm$ SEM ($n = 6$ in each group). *, # $p < 0.05$ compared to IC (infected not treated control), 30CHQ (30mg/kg chloroquine)-pectin patch, respectively.

Figure 5. AA5-TDDS (AA 5mg/kg transdermal drug delivery system) influence on absolute Na^+ excretion compared to controls. Results presented as mean $\pm$ SEM ($n = 6$ in each group). *, # $p < 0.05$ compared to IC (infected not treated control), 30CHQ (30mg/kg chloroquine)-pectin patch, respectively.

3.7. Influence of AA5-Pectin Patch on Aldosterone

Hormonal renal modulation of electrolyte handling was indicated by concentrations of ALD. A comparison of the influence of AA-pectin patch on ALD with controls was (Figure 7). Application of AA5-pectin patch significantly reduced ALD ($p < 0.05$, compared to IC and CHQ, respectively).

Figure 6. A comparison of AA5-TDDS (AA 5mg/kg transdermal drug delivery system) influence on ALD against controls. Results presented as mean $\pm$ SEM ($n = 6$ per group). *, # $p < 0.05$ compared to NIC (non-infected control), IC (infected not treated control) and CHQ (30mg/kg chloroquine), respectively.

3.8. Influence of AA5-Pectin Patch on AVP Secretion

Dehydration status and water balance was reflected by AVP concentrations in plasma. The influence of AA-pectin patch application is compared to controls (Figure7). Once-off AA-pectin patch application suppressed AVP significantly

compared to both the IC and CHQ patch ($p < 0.05$, respectively). Influence of AA5-pectin patch on superoxide dismutase (SOD): Oxidative status of the animals administered AA, CHQ and IC groups was indicated by SOD concentration in tissues of the kidney. The influence of AA5-pectin patch application on SOD activity is compared to control animals (Table 4 [A]). Compared to IC and CHQ, AA5-pectin patch administration did significantly increase enzyme activity ($p < 0.05$) in kidney. Influence of AA5-pectin patch on glutathione peroxidase (GPx): Oxidative status of the animals administered AA, CHQ and IC groups was indicated by GPx concentration in tissues of the kidney. AA5-pectin patch influence on GPx was compared to control animal groups in (Table 4 [B]). Influence of AA5-pectin patch on malonyldialdehyde (MDA): The level of lipid peroxidation, a marker of oxidative stress in malaria, was reflected by amount of MDA in the kidney tissues. The levels of MDA in AA-pectin patch applied animals was compared to controls (Table 4 [C]). AA5-pectin patch significantly reduced levels of MDA in kidney compared to IC ($p < 0.05$).

Figure 7. Influence of AA5-TDDS (AA 5mg/kg transdermal drug delivery system) application compared with controls. Results presented as mean $\pm$ SEM ($n = 6$ per group). *, # $p < 0.05$ compared to NIC (non-infected control), IC (infected not treated control) and CHQ (30mg/kg chloroquine), respectively.

Table 4. AA5-pectin patch effects on antioxidant status compared to controls. Superoxide dismutase (SOD), GPx and malonyldialdehyde (MDA) were determined. Values are presented as means $\pm$ SEM ($n =$ per group). *, # $p < 0.05$ compared to the NIC (non-infected control), IC (infected not treated control) and CHQ (30mg/kg chloroquine), respectively.

Measured parameter	Experimental group	Tissue source/organ
		Kidney
[A] SOD activity (mU/mL)	NIC	26.34 $\pm$ 13.6
	IC	2.58 $\pm$ 2.9
	CHQ 30mg/kg	12.11 $\pm$ 3.7

4. Discussion

The systemic pathophysiology of malaria acute renal failure requires a wholesome approach bed-rocked on antimalarial agents with multiple anti-inflammatory properties, divergent from parasite load-reduction approaches [24]. We, therefore, report here for the very first time, the influence of transdermal drug delivery system of Asiatic acid on renal function and electrolyte handling in *P. berghei*-infected SD male rats. This approach qualifies to be regarded as an anti-disease paradigm.

The combination of amphiphilic Asiatic acid and transdermal drug delivery system provide a robust framework for combating malaria providing a revolutionary way in which malaria may be managed. Asiatic acid-hydrogel matrix application provides a once-off treatment for malaria, in its own way, a drastic divergence from the known convoluted regimens of current antimalarial drugs in both dose, dosage frequency and administration route. The theoretic concentration delivered into the systemic circulation was several amplitudes lower than either oral or transdermal drug delivery system chloroquine at 3µg/kg (6.14nmol/L) giving credence to the efficacy of Asiatic acid 5mg/kg-transdermal drug delivery system malaria suppression. In our laboratory, malaria posology is designed for a five day twice daily treatment course but Asiatic acid-transdermal drug delivery system reduced treatment to a once-off-three-day treatment protocol. This prototype reduced animal manipulation frequency, stress and conferred improved food and water intake as well as % weight gain. Continued feed observed during infection is tacit indication of the animal overcoming the sickness behaviour which is characterised by food and water intake aversion, anorexia, cachexia and death.

Post-infection application of the patch preserved the animal wellbeing in general with profound effect of renal function and electrolyte handling. Indeed, malaria and malnutrition from inadequate food intake co-exist as factors contributing to high mortality in children [15]. An anorexic exposition in the infected non-treated animals (absent from Asiatic acid-transdermal drug delivery system treated animals) was typified by a negative % weight gain by day 12 making it necessary to humanely dispose those affected animals.

The preserved bio-physicochemical characteristic of animals on Asiatic acid 5mg/kg-pectin patch resulted in the improved glomerular filtration rate compared to either chloroquine 30mg/kg-patch or the infected non-treated animals. The influence of Asiatic acid on renal function is only limited to a report on *Centella asiatica* having diuretic effect cited by Singh et al (2010) from an untraceable source [44], making this current report the first to show improved glomerular filtration rate from Asiatic acid-transdermal drug delivery system administration. Moreover, the anti-parasitic efficacy of Asiatic acid has been reported recently in pre- and post-infection oral administration of Asiatic acid (10mg/kg) to animal experiment [21, 22]. Treatment with chloroquine patch resulted in a higher glomerular filtration rate during the treatment period as has been reported that chloroquine

inhibits arginine vasopressin (antidiuretic hormone) which will invariably increase urine output and glomerular filtration rate [29] leading to hypovolaemia, dehydration and increased arginine vasopressin concentration in return. Observations have also been made that oral chloroquine administration has more pronounced effects on glomerular filtration rate than transdermal drug delivery system chloroquine [28] and Asiatic acid-transdermal drug delivery system seem to have the opposite effect. Furthermore, Patel *et al* (2015), using silico structure-based virtual screening approach have shown Asiatic acid to be non-nephrotoxic [36] which effect has been corroborated by current findings that Asiatic acid-transdermal drug delivery system had protective effect in malaria shown by the recovery and preservation of glomerular filtration rate.

The influence of Asiatic acid-transdermal drug delivery system application on urine Na⁺ output was significantly lower compared to the infected non-treated control and chloroquine-patch treatment. However, there was an increase in urine Na⁺ output on day 7, at the initiation of treatment, which was reflected by a non-significant inflection in the glomerular filtration rate when compared to the non-infected treated control during the pertinent time point which we could not explain based on these results. We, however, speculate as an interpretation, that the observed urine Na⁺ output rise could have been a parasite induced effect as this trend was similar to the infected non-treated control urine Na⁺ output and glomerular filtration rate. The initial diffusion, for lack of knowledge on the Asiatic acid transportation mechanism through the dermis at present, into the systemic circulation may have coincided with an increase in parasitaemia causing a fall in glomerular filtration rate and subsequently a rise in urine Na⁺ output. A cursory inspection of the % parasitaemia will show that indeed, there was a higher transition in parasitaemia between pre-patent (day 3) and the patent/treatment (day 7) periods in the order of 14.19% >9.5% >8.16% for Asiatic acid, infected non-treated control and chloroquine, respectively. It may also be instructive to mention that a single urine Na⁺ output is more an indication of the concentration of the urine and its volume, in the absence of the urine osmolality and may not be reflective of incipient kidneys disease. Our observations were the higher the urine Na⁺ the less urine volume excreted and the more concentrated the urine was. The homeostasis of urine outflow, by convention, depends on a variety of factors to include water intake. We were able to demonstrate that the Asiatic acid-pectin patch applied animals did preserve their water intake for the duration of the study. However, a constantly higher and rising urine Na⁺ may have indicated kidney disease as we observed with the infected non-treated control and chloroquine-patch groups.

Other researcher have shown that malaria induces increased Na⁺ excretion through the induction of nitric oxide (NO) [10, 41]. Inducible nitric oxide synthesis (iNOS) is upregulated in malaria generating excessive NO, a soluble gas synthesized from L-arginine, which inhibits Na⁺/K⁺ ATPase pump responsible for the active reabsorption of the

ion in the proximal convoluted tubules and other cells. When combined with oxygen, NO forms peroxynitrite (ONOO⁻) a highly oxidative compound which might be responsible for inhibition of the Na⁺ transporters.

Asiatic acid has been suggested to inhibit iNOS, cyclooxygenase-2, interleukin-6, interleukin-1 β and tumour necrosis factor- α expression by downregulating nuclear factor-kappa beta via I κ B kinase and mitogen-activated protein kinase [12]. These inflammatory mediators are invariably upregulated in malaria. The anti-inflammatory effect of Asiatic acid has been demonstrated in other studies. There is a higher probability that the preservation of Na⁺ excretion could be through the Asiatic acid-transdermal drug delivery system administration induced protection of the Na⁺/K⁺ ATPase from oxidative inhibition. The infected non-treated control group had significantly higher Na⁺ excretion. On the other hand, chloroquine-patch high Na⁺ urine excretion during patent/treatment period and beyond was expected as from previous studies. Other researchers have reported that chloroquine increases renal Na⁺ excretion by inhibiting AVP or ADH [30, 31]. Synergistic effects of the parasite and chloroquine in Na⁺ depletion may be involved in the hyponatraemia of malaria and may persist after successful disease treatment [47].

The absolute urine Na⁺ excretion was observed to be continuously rising in the infected non-treated controls showing a sodium wasting process through transporters inhibition. We cannot currently explain why the parasite causes Na⁺ depletion, weakening its own survival chances with the demise of the host. We speculate that an excessive Na⁺ diuresis is not an intended outcome by the parasite. A sequelae from host over-responsiveness to infection through immune reactivity, oxidative stress and inflammation might also be at play. These aspects were resolved by the application of Asiatic acid-amidated pectin patch in our experiments as compared to infected non-treated control and chloroquine. This may suggest that application of Asiatic acid-transdermal drug delivery system may have an anti-disease effect on renal Na⁺ handling through restoration of the Na⁺/K⁺ ATPase pump or preservation of other mechanism affected by malaria infection.

The urine K⁺ output was significantly elevated in the untreated as well as the chloroquine patch treated animal groups when compared to the Asiatic acid-pectin patch treated animals. This was possibly a reflection of the hyperkalaemia occurring as result of the ATPase pump failure to maintain Na⁺ within the extracellular compartment as well as increased haemolysis. The ATPase pump does not affect renal electrolyte handling only but most cell membranes including red blood cells (RBC's) with subsequent K⁺ movement into the extracellular space.

The wider ramification of inflammation driven NO excess tends to affect RBC's metabolism and membrane integrity and deformability which results in RBC's (both parasitized-pRBC's and non-parasitized-npRBC's) removal by the spleen [19] with resultant severe malaria anaemia [8]. We did not observe a rise in urine K⁺ output in the AA5-pectin patch

applied animals in contrast to the infected non-treated animals and the chloroquine-patch treated animals. This may indicate a reduction or absence of haemolysis which may be traced back to the anti-inflammatory effect of Asiatic acid on RBC membrane integrity. The antioxidant capacity of AA could also have quenched ROS generation while the pro-oxidant capacity may have eradicated the parasite to preserve the kidney function.

To corroborate the renal electrolyte preservation capacity of AA5-pectin patch was the estimation of urine Cl⁻ output. Urine Cl⁻ output was elevated in the IC as well as the chloroquine-patch treated animals, but remained significantly correlated to the non-infected treated animals' values except during treatment. Noteworthy is the fact that, application of the Asiatic acid-pectin patch was commenced when the parasitaemia had already reached patent and stable state and the reversal of the electrolyte dysregulation observed for Cl⁻ but not observed in the infected non-treated animals urine Cl⁻ output indicated the influence of Asiatic acid on renal electrolyte handling. An increase in urine Cl⁻ output, besides depicting a concentrated urine excretion, may also be an indicator of acid base balance disturbances. In non-respiratory acidosis there is a depletion of HCO₃⁻ and an increase in H⁺ which necessitates conservation of the latter in the proximal convoluted tubules. To maintain an electrolyte neutrality, Cl⁻ shifts from the tubular cells into the lumen in exchange and preservation of HCO₃⁻. The hydronium ion is also excreted in exchange for K⁺ or Na⁺ but due the ATPase pump failure in malaria, this may not happen. As a result non-respiratory acidosis escalates worsening the compromised renal function.

Besides impairment of Na⁺/K⁺ ATPase pump by increased oxidative stress, ATP rundown seen in malaria through Poly (ADP-ribose) polymerase activation by ONOO⁻ in malaria may also contribute to pump failure with the same results. Besides inhibition of Na⁺/K⁺ ATPase pump, NO also inhibits endothelial Na⁺ channels (ENaC). Other electrolyte transporters such as the Na⁺/H⁺ exchanger that facilitate proton excretion and HCO₃⁻ reabsorption depend on the Na⁺ electrochemical gradient created by the ATPase. Inhibition of the pump may, therefore, result in acidosis [5]. However, Asiatic acid has been reported to alleviate haemodynamic and metabolic aberrations in rats with metabolic syndrome via the equilibration of endothelial nitric oxide synthase (eNOS) and induced nitric oxide synthase expression together with oxidative stress and inflammation reduction [35]. These reports are in support of our findings that Asiatic acid-pectin patch application suppressed parasitaemia as well as the abolition of other malaria pathophysiology.

Due to the inhibition of ENaC, aldosterone is unable to effect Na⁺ retention resulting in salt-losing nephropathy characterised by dehydration and non-respiratory acidosis and a concomitant rise in the hormone's plasma concentration. When aldosterone activity is elevated, in rising natriuresis, a condition termed pseudohypoaldosteronism type 1 results in congenital conditions characterised by ENaC failure [2]. We observed

the same scenario during the initiation of AA-TDDS application on day 8. Significantly higher activity of aldosterone corresponded to raised urine Na^+ output and a downward transitory inflection in the glomerular filtration rate which could indicate hypovolaemia from reduced food and water intake, increased RBC's destruction or both. This may also imply that before therapeutic dose of Asiatic acid was reached, there might have been inhibition of the ENaC resulting in hyperaldosteronism. Reactivation of the channel, through possible quenching of oxidative stress or oxygen reactive species or both might have normalized Na^+ excretion. In stark contrast to Asiatic acid-pectin patch effect was the infected non-treated and chloroquine-patch treated controls showing raised aldosterone and urine Na^+ concentrations, indications of possible excessive ATPase pump inhibition.

AVP activity for Asiatic acid-pectin patch applied animals, during the day 8 time-point, was higher than for other time-points triggered by possible hypovolaemia and increasing osmolality. However, the activity was comparatively lower than both the infected non-treated and chloroquine-patch treated groups. Indeed, chloroquine has been shown to influence increased Na^+ urine excretion [31] through inhibition of cyclic AMP (cAMP) or via generation of NO [1]. Both mechanism cause an increase in plasma vasopressin as we observed in these experiments. The resultant diuresis and natriuresis are hall marks of chloroquine treatment which we were corrected in Asiatic acid-transdermal drug delivery system application. In contrast to this finding, *C. asiatica* extract has been reported to increase cAMP content in tissues [46]. Asiatic acid could have used the same mechanism in preservation of renal electrolyte handling.

To probe further the influence of Asiatic acid-transdermal drug delivery system on oxidative stress, we measured the activity of antioxidant enzymes and the level of peroxidation in the kidney. Significantly higher superoxide dismutase activity was observed in the animals on Asiatic acid-pectin patch. Also, significantly raised was glutathione peroxidase from Asiatic acid-transdermal drug delivery system patched animals as compared to both the infected non-treated and the chloroquine-patch treated animals. On the other hand animals applied the Asiatic acid-TDDS patch had lower MDA compared to the chloroquine-patch and the infected non-treated groups. Others workers have also described similar findings with oral administration of Asiatic acid at higher doses, than reported here, in non-malaria conditions [12]. The antioxidant role of Asiatic acid-pectin patch in the preservation of renal electrolyte handling may have been through reactivation of the ATPase pump as well as hormonal influence of water metabolism showing possible anti-disease effects of Asiatic acid on kidney function. Further work, however, may be needed to explore the possible interaction of Asiatic acid with electrolyte channels and transporters, the interaction of Asiatic acid with malaria toxins that elicit inflammatory reactions and the general metabolic effects of the amphiphilic nature of Asiatic acid in malaria.

5. Conclusion

It has been able to demonstrated that AA5-amidated pectin hydrogel matrix patch application reduced the dosing frequency, dosage and the duration of treatment. Also shown was the ability of Asiatic acid-pectin patch application to preserve food and water intake as well as weight gain and suppress parasitaemia. Asiatic acid-transdermal drug delivery system ameliorated the disease aspect of malaria through increasing antioxidant capacity, reduction in renal lipid peroxidation, preservation of renal function and electrolyte homeostasis together with maintenance of renal hormonal function. In addition, it was observed that pseudohypoaldosteronism was a reversible condition in malaria with proper treatment as a slight increase in urine Na^+ output was attenuated by Asiatic acid-transdermal drug delivery system application. Speculation is made in this research that the antioxidant capacity of Asiatic acid-transdermal drug delivery system through quenching of NO, ROS, ONOO⁻ seem to influence renal function and electrolyte handling through preservation of the Na^+/K^+ ATPase pump and ENaC. These findings warrant possible application of Asiatic acid-transdermal drug delivery system as antimalarial therapy in the future.

Acknowledgements

Honour goes posthumously, to Professor Cephas Tagumirwa Musabayane the dearly beloved, departed supervisor and mentor of this work. Professor Fanie R Van Heerden is highly honoured for the initial AA that allowed this project to start. The Discipline of Physiology Endocrinology Group, Mr. M. Luvuno in particular, is highly appreciated for the tremendous contributions in animal and laboratory experiments. Special mention is herein made of the contributions of Ms Sibiya HP and Mbatha B whose animal handling techniques whetted the author's skills in this field. This study was made possible through University of KwaZulu Natal, College of Health Sciences (CHS) scholarship granted (CHS 213574054) obtained by the first author (GAM).

Conflict of Interests

All the authors do not have any possible conflicts of interest.
