Abstract: To explore the amount of reducing N fertilizer, a 2-year field experiment was conducted to investigate the effects of reducing N fertilizer and applying organic fertilizer on nitrogen use efficiency (NUE) and rice yield in red soil regions of the Southern China. On the basis of applying 4500 kg/ha organic fertilizer and local custom fertilization with 204 kg/ha urea application, five treatments including no nitrogen fertilization (CK), local customary nitrogen application (N100), and nitrogen reduction of 10% (N90), 20% (N80), and 30% (N70) were conducted. The results showed that nitrogen agronomic efficiency (NAE), nitrogen recovery efficiency (NRE), nitrogen physiological efficiency (NPE) and nitrogen partial factor productivity (NFPF) of N90 treatment were significantly higher than those of other treatments, and the yield was as high as 9.33 t/ha, which showed a significant differences compared with CK and N100. The output value, benefit, and benefit-cost ratio of N90 were significantly higher than those of N100, which increased by 6.38%, 6.42%, 8.35%, and 8.20%, respectively. In addition, while applying the same amount of organic fertilizer, the rate of nitrogen reduction has little effect on the soil organic matter content, meaning that N90 can achieve high NUE and high yield in rice. It is good to provide the theory basis for fertilizer decision-making in practice.

Keywords: Red Soil Regions of the Southern China, Reduced Nitrogen Application, Organic Fertilizer Application, Nitrogen Use Efficiency

1. Introduction

Study has suggested that adequate fertilization is important for plant growth healthily with high crop yield [18]. With the improvement of agricultural intensification in China, the amount of chemical fertilizers has increased significantly. Grain production is characterized by high input and high yield in China, the amount of nitrogen fertilizer accounts for 30% of the world's nitrogen use, and the nitrogen fertilizer used in rice production accounts for 37% of the world's nitrogen fertilizer, the amount nitrogen fertilizer in China is about 75% higher than the average amount of that in the world [13]. Zhang summarized the results of 1333 field trials in China's major grain production areas in recent years, and found that the nitrogen use efficiency of major grain crops was 10.8%-40.5%

in China, with an average of 27.5%, far lower than the world level of 40%-60% [5, 22]. The serious loss of soil nitrogen and the low nitrogen use efficiency are one of the important problems that restrict the development of high-yield, efficient and high-quality agriculture in China. How to improve the soil nitrogen supply capacity, reduce the loss of nitrogen nutrients, and enhance the nitrogen use efficiency is an important issue that needs to be solved urgently. Excessive nitrogen fertilizer input in paddy field will result in not only acidification of the soil and reducing nitrogen use efficiency, but also a series of environmental problems [11, 14]. Meanwhile, the organic fertilizer application has gradually decreased. In this regard, the combination of organic and inorganic fertilizers may be a possible remedy to increase yields and avoid environmental pollution, especially in rice fields. The application of organic

fertilizer can greatly improve the negative impact of single application of chemical fertilizers on the soil and the environment. It has been shown that single application of organic fertilizer or combined application of chemical fertilizers can effectively increase soil organic matter content, soil enzyme activity and crop yields [8, 22]. Relevant research proves that the combined application of organic and chemical fertilizers is beneficial to improve the crop nitrogen use efficiency [1, 12]. Results from different studies revealed that continuous application of farmyard manure and green manure improved the soil organic carbon under different soils and cropping systems, therefore any nutrient management practice that can improve soil organic matter which sustaining crop productivity and reduce the amount of chemical fertilizers, use efficiency of agricultural waste resources and ease the pressure on the environment [3, 21].

In order to improve rice yield and nutrient use efficiency, many experiments have been conducted on paddy fields during the past decades, which most studies focusing on the effects of single inorganic fertilizer or combined organic fertilizer on rice production or NUE, but the effect of reducing N fertilizer and applying of organic fertilizer on nitrogen use efficiency and rice yield was rarely reported, especially in red soil regions of the Southern China. Therefore, we conducted

the experiment (1) to comprehensively evaluate the effect of different reducing N fertilizer ratio on rice yield and NUE, compared to local customary nitrogen application (N100), (2) to investigate how the yield components varies with the different reducing N fertilizer ratio, and (3) to determine the ratio reducing N fertilizer when applying adequate organic fertilizer.

2. Materials and Methods

2.1. Experimental Site

The experiments were carried out at the agricultural experiment station (115°25'E, N27°42'N), Rongtang Town of Fengcheng, Jiangxi Province in China during the 2017-2018 rice-growing season. The experimental site was situated in a subtropical humid region, with an average annual rainfall of 1,500 mm. Average annual sunshine was 1935.7 h, average annual temperature was 15.3-17.7°C, maximum average humidity was 81%.

Pre-experiment analysis showed that paddy field soil was medium loam. The basic physical and chemical properties of the soil are shown in Table 1.

Table 1. Basic properties of top soil (0-20 cm) tested.

Organic matter (g/kg)	pH	Hydrolyze N (mg/kg)	Available P (mg/kg)	Available K (mg/kg)
46.00	5.01	225.10	26.02	135.50

2.2. Experimental Design

Paddy rice (Zhuliangyou 718) was grown in completely randomized blocks with plot size of 126 m², the fertilization treatments were designed as follows: no nitrogen fertilization (CK), local customary nitrogen application (N100), and nitrogen reduction of 10% (N90), 20% (N80), and 30% (N70), on the basis of applying 4500 kg/ha organic fertilizer and local

custom fertilization with 94 kg/ha nitrogen fertilizer. There were four replications which was arranged in a randomized block design in our field experiment. Transplanting was conducted at a space of 0.25 m × 0.14 m with two seedlings per hill. Other managements, such as irrigation and insects followed the local high-yielding practice. The details of experimental design were listed in Table 2. Sampling and Laboratory Procedures

Table 2. Fertilization amount under different nitrogen reduction treatments.

Treatment	Urea (kg/ha)	Kcl (kg/ha)	Calcium magnesium phosphate (kg/ha)	Organic fertilizer (kg/ha)
CK	0	87	300	4500
N100	204	87	300	4500
N90	169.5	87	300	4500
N80	133.5	87	300	4500
N70	97.5	87	300	4500

The test fertilizers are urea (N 46%), superphosphate (P₂O₅ 12%), potassium chloride (K₂O 60%); the organic fertilizer (N 1.57%, organic matter >45%) produced by Jiujiang Lilai Biotechnology company.

We selected 5 m² areas in the middle of each plot to determine grain yields at harvest. Yields were adjusted to 14% moisture content fresh weight. At maturity, we counted the panicle numbers for 4 m² areas (30 hills), and the 12 hills of each treatment were divided into their above-ground parts to determine the total dry weights and yield formations.

Rice plants were dried at 105°C for 30 min in the oven and then at 85°C to get a constant weight then digested with H₂SO₄-H₂O₂ at 265°C. An Autoanalyser 3 Digital Colourmeter (Bran+Luebbe Inc., Norderstedt, Germany) was used to determine the total N concentration.

Some indicators were calculated as given in Eqs. (1)-(5):

$$\text{Total nitrogen accumulation (kg/ha)} = \text{aboveground biomass per unit area} \times \text{plant nitrogen content} \quad (1)$$

$$\text{Nitrogen recovery efficiency} = \frac{\text{nitrogen absorption of plants in nitrogen application plot} - \text{nitrogen absorption of plants in blank plot}}{\text{nitrogen application amount}} \times 100\% \quad (2)$$

$$\text{Nitrogen agronomic efficiency (kg /kg)} = \frac{\text{grain yield in nitrogen application plot} - \text{grain yield in blank plot}}{\text{nitrogen application amount}} \quad (3)$$

$$\text{Nitrogen physiological efficiency (kg /kg)} = \frac{\text{Grain yield in nitrogen application plot} - \text{grain yield in blank plot}}{\text{Nitrogen uptake of plants in nitrogen application plot} - \text{Nitrogen uptake of plants in blank plot}} \quad (4)$$

$$\text{Nitrogen partial factor productivity (kg /kg)} = \frac{\text{yield in nitrogen application plot}}{\text{nitrogen fertilizer application amount}} \quad (5)$$

2.3. Data Analysis

Statistical evaluation of the data was performed by SPSS Statistics 25.0 (SPSS Armonk, NY: IBM Corp; 2019). The data were analyzed first by a one-way ANOVA, followed by Duncan's test if a significant difference was determined. Data are shown as mean \pm standard error (n=4). All figures were generated with Micro Office Excel 2013. The differences between treatments are compared according to the least significant difference test (at a probability level of 5%).

3. Results

3.1. Rice Yield and Yield Components

Date for rice yield and yield components under different treatments were presented in Table 3. Except for 1,000-grain weight, the panicle number plant⁻¹, the number of spikelets panicle⁻¹, the seed setting rate and the actual yield of the CK

treatment were significantly lower than those of other treatments. Thus it can be seen that nitrogen fertilizer significantly affects rice yield and yield components.

Significant difference was observed in the panicle number plant⁻¹ among all the treatments, it was same with the number of spikelets panicle⁻¹ excepting for N100 and N70. Rice yield and yield components (excepting for 1,000-grain weight) of N90 were observed significantly higher than other treatment, and theoretical yield was presented as the order: N90 > N800 > N100 > N70 > CK, the actual yield was presented as the order: N90 > N100 > N80 > N70 > CK. The theoretical yield and actual yield of N90 treatment were 26.38% and 6.39% significantly higher than N100, respectively. In addition, we can find a surprising that there were no differences for 1,000-grain weight among the all treatments, which indicated that 1,000-grain weight is an inherent attribute of the rice variety.

Table 3. Effects of different treatments on rice yield and yield components.

Treatment	Panicles 10 ⁴ /ha	Spikelets per panicle	Seed setting rate (%)	1,000-grain weight (g)	Theoretical yield (t/ha)	Actual yield (t/ha)
CK	268.50 \pm 1.39 e	83.90 \pm 0.26 d	82.03 \pm 0.19 c	23.02 \pm 0.15 b	5.19 \pm 0.08 d	6.39 \pm 0.04 d
N100	390.00 \pm 0.63 a	96.10 \pm 0.16 c	93.39 \pm 0.21 a	23.66 \pm 0.21 ab	8.87 \pm 0.12 b	8.77 \pm 0.06 b
N90	373.50 \pm 1.82 b	125.60 \pm 0.31 b	91.55 \pm 0.26 b	23.89 \pm 0.16 ab	11.21 \pm 0.12 a	9.33 \pm 0.16 a
N80	345.00 \pm 0.55 c	131.90 \pm 0.10 a	94.15 \pm 0.08 a	23.76 \pm 0.17 ab	10.81 \pm 0.14 a	8.22 \pm 0.03 c
N70	337.50 \pm 0.33 d	97.01 \pm 0.06 c	93.90 \pm 0.17 a	24.60 \pm 0.31 a	8.05 \pm 0.05 c	7.90 \pm 0.13 c

Within treatment, means followed by different letters are significantly different according to LSD ($p \leq 0.05$).

3.2. Nitrogen Efficiency in Rice

As shown in Table 4, nitrogen agronomic efficiency of N90 was significantly higher than other treatments, which is 36.98%, 43.23% and 51.57% more than N100, N80 and N70, respectively. It was same with nitrogen recovery efficiency but except for N100. Nitrogen physiological efficiency of N90 was the highest and there was significant difference compared with N100. Nitrogen partial factor productivity showed an

upward trend gradually with the increasing of the nitrogen fertilizer reduction, it was observed that N70 was significantly higher than other treatments, which were 28.28%, 8.92% and 9.93% more than N100, N90 and N80 treatments, respectively. The results of the study showed that reducing the nitrogen fertilizer application rate by 10% can improve the nitrogen efficiency in rice, it is consistent with the research of Liu [9].

Table 4. Effects of different treatments on nitrogen use efficiency.

Treatment	NAE (kg/kg)	NRE (%)	NPE (kg/kg)	NPEP (kg/kg)
N100	14.44 \pm 0.21 bc	33.64 \pm 1.42 a	43.11 \pm 1.98 b	53.32 \pm 0.36 c
N90	19.78 \pm 1.06 a	34.76 \pm 1.92 a	57.28 \pm 4.55 a	62.80 \pm 1.06 b
N80	13.81 \pm 0.26 c	26.75 \pm 1.77 b	51.99 \pm 3.05 ab	62.22 \pm 0.20 b
N70	13.05 \pm 1.42 c	24.53 \pm 1.76 b	52.90 \pm 1.66 ab	68.40 \pm 1.66 a

Within treatment, means followed by different letters are significantly different according to LSD ($p \leq 0.05$). Nitrogen agronomy efficiency (NAE), Nitrogen recovery efficiency (NRE), Nitrogen physiological efficiency (NPE), Nitrogen partial factor productivity (NPEP).

3.3. Economic Benefit of Rice Production

Date for yield, output value, fertilizer cost, benefit and benefit-cost ratio were presented in Table 5. All indicators of treatment N90 (except for fertilizer cost) were significantly

higher than that of other treatments. Compared with N100, yield, output value, benefit and benefit-cost ratio of N90 showed significant differences, increased by 6.38%, 6.42%, 8.35% and 8.20%, respectively. In addition, these indicators showed the following rules: N90 > N100 > N80 > N70.

Considering synthetically these economic indicators such as fertilizer cost, output value, benefit and benefit-cost ratio, it was not difficult to find that N90 was the most suitable

treatment to recommend. It can not only further control and reduce fertilizer costs, but also achieve higher output value and benefit-cost ratio.

Table 5. Effects of different treatments on benefit of rice production.

Treatments	Yield (t/ha)	Output value (RMB/ha)	Chemical fertilizer cost (RMB/ha)	Organic fertilizer cost (RMB/ha)	Benefit (RMB/ha)	Benefit-cost ratio
N100	8.77±0.06b	22802.22±152.35 b	852.72	3600	18349.28±152.35 b	5.12±0.04 b
N90	9.33±0.16a	24266.67±409.82 a	784.41	3600	19882.26±409.81 a	5.54±0.09 a
N80	8.22±0.03c	21363.33±67.69 c	713.13	3600	17050.20±67.69 c	4.95±0.02 bc
N70	7.90±0.13c	20540.00±338.00 c	641.85	3600	16298.15±338.00 c	4.84±0.08 c

Within treatment, means followed by different letters are significantly different according to LSD ($p \leq 0.05$).

3.4. Soil Organic Matter Content

As shown in Figure 1, the soil organic matter content of each treatment was ranked as N80 > N90 > N70 > N100 > CK > Basic soil (Basic soil samples collected before the experiment). The soil organic matter content of all treatments applied with organic fertilizer were significantly higher than Basic soil, increased by 15.87%, 14.35%, 13.91%, 12.83% and 11.74% respectively. Except for N80 and N90, no significant difference was found in the soil organic matter content among treatments applied with organic fertilizer. Interestingly, no significant difference was found between the CK without nitrogen fertilizer and other treatments. Importantly, data in Figure 1 showed a significant effect on the soil organic matter content when applying organic fertilizer. So the amount of nitrogen reduction had little effect on the soil organic matter content. This result may indicate that nitrogen fertilizer can significantly affect rice yield, but the increase of soil fertility is due to organic fertilizer.

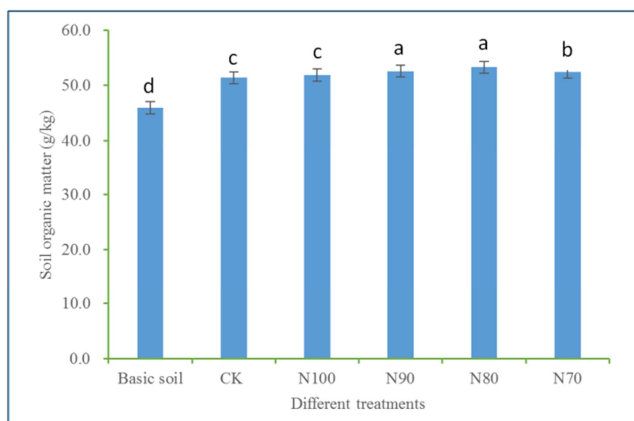

Figure 1. Effects of different treatments on soil organic matter content.

4. Discussion

4.1. Effect on Yield and Yield Formation Factors

Nitrogen is one of the main nutrients for rice growth and development, which has an important impact on the formation of rice yield and can significantly increase the panicle number plant⁻¹ and the number of spikelets panicle⁻¹, tillering is significantly influenced by N concentration [19]. But in this study, there was no significant difference in yield among the

treatments applied with N fertilizer. The number of panicle did not increase continuously with the increase of N. Zhong reported that tillering is not only affected by nutrients, but also by space [24]. At present, many studies have shown that in the optimization of nitrogen treatment, the number of spikelets per panicle is more than that of farmers' fertilization practice management. [6, 15]. Combined application of organic and chemical fertilizers can increase the net photosynthetic rate of functional leaves and increase the accumulation of dry matter in the early stage of rice, thereby increasing rice yield [10, 16]. Yi showed that compared with the local customary nitrogen fertilization, the rice yield in the first season of 20% nitrogen reduction did not significantly decrease, while the nitrogen agronomic efficiency and nitrogen partial factor productivity has increased [20]. In our study, N90 of 10% N fertilizer reduction got the yield as high as 9.33 t/ha, which was significantly higher than CK and N100. Compared with N100, the output value, benefit, and benefit-cost ratio of N90 increased significantly by 6.38%, 6.42%, 8.35%, and 8.20%, respectively.

4.2. Effect on Nitrogen Efficiency in Rice

The continuous increase of grain yield in China is based on the increasing input of nitrogen fertilizer. From the early 1990s, the problems of excessive nitrogen fertilizer input and low use efficiency began to surface in china's crop production [4]. Zhu found that the nitrogen use efficiency was as low as 20%-35%, chemical fertilizer combined with organic fertilizer can not only reduce the input of chemical fertilizer, but also promote the transport of nitrogen in vegetative organs and increase the rice yield [25]. Li indicated that the application of organic fertilizer can promote the fixation of nitrogen microbes and increase nitrogen use efficiency [7]. Zhang showed that applying nitrogen with 140 kg/ha, the economic benefits of rice production and nitrogen use efficiency were the highest, the nitrogen agronomic efficiency and nitrogen partial factor productivity were 11.5 and 63.2 kg/kg, respectively [23]. Our study showed that combined application of organic fertilizer, 10% reduction in nitrogen significantly improved the nitrogen agronomic efficiency and the nitrogen recovery efficiency, which were as high as 19.78% and 34.76%. And the treatments of reducing nitrogen by 10%, 20% and 30% significantly improved the nitrogen physiological efficiency and nitrogen partial factor productivity, significant

differences were observed compared with N100.

4.3. Effect on Soil Organic Matter Content

The soil organic matter content can directly reflect the level of the soil fertility. Organic fertilizer has an extremely significant role in increasing soil nutrition and improving soil structure [17]. Organic matter directly affects the growth and yield of crops by providing nutrients, and indirectly improves the root environment and stimulates plant growth by changing the physical properties of the soil (such as the stability and porosity of aggregates), thereby indirectly affecting the growth and yield of crops [2].

Combined application of organic fertilizer and chemical fertilizer can not only ensure adequate available nutrients but also reduce nutrient loss and improve fertilizer use efficiency, thereby significantly increasing rice yield. Our results showed that the soil organic matter content of the treatments applied with organic fertilizer was significantly higher than that of the basic soil (sampled before the test). Except for N80, no significant difference in soil organic matter content was found among all the treatments, which indicated that while applying the same amount of organic fertilizer, the amount of nitrogen reduction has little effect on the soil organic matter content.

5. Conclusion

Thus from the present investigation it may be concluded that combined use of organic fertilizer at 4500 kg/ha and nitrogen reduction by 10% (N90) resulted in the significant improvement in yield and benefit-cost ratio in rice production and increase of nitrogen use efficiency. It was also observed that combined use of organic fertilizer at 4500 kg/ha and nitrogen reduction by 10% (N90) led to improvement in soil organic matter content, the amount of nitrogen reduction has little effect on the soil organic matter content while applying the same amount of organic fertilizer. So combined use of organic fertilizer at 4500 kg/ha and nitrogen reduction by 10% (N90) may be practiced in red soil regions of the South China to improve soil physical environment and enhance soil organic matter and for achieving higher yield through efficient utilization of nitrogen in rice.
