Abstract: The general objective of this work was to assess approaches used by the nurses at the Laquintinie Hospital Douala in the care of patients with NG Tubes and so identify the challenges nurses faced when caring for patients with NG tubes. It was a descriptive cross sectional study design carried out from April to June, the sample technique and study population involved 20 nurses working at the medical, paediatric intensive care unit and the surgical unit, the data was collected using an observation and interview guide. The result collected shows that only (53%) of the nurse were able to manage patient effectively. From the findings of this work it is concluded that only few of the nurses could actually carry out care on patient with NG tubes effectively and all (75%) of the nurses who had carried out nasogastric intubation on patients had challenges like patient refusal to cooperate as they were educated on the importance of the procedure. Based on the findings the following recommendations were made like, the nurses at the L.H.D should attend seminars on the different strategies used in the care of patients with NG tubes. The nurses should also go in for more research on internet, textbooks and journals.

Keywords: Nasogastric, Intubation, Patience, Cameroon

1. Introduction

Nasogastric intubation is a medical process involving the insertion of a plastic tube (Nasogastric tube or NG Tube) through the nose, past the throat, and down into the stomach. [1] Orogastric intubation is a similar process involving the insertion of a plastic tube (Orogastric Tube) through the mouth. Nasogastric feeding is usually considered as the first line in artificial nutrition support for patients with a functioning gastrointestinal tract whose nutritional needs cannot be met by diet alone or by diet and nutritional supplements. [1, 2]

Nasogastric gastric tube insertions are carried on by nurses, junior doctors and sometimes by anaesthetists in the theatre. [1-3] A registered nurse may commence NG tube once it has been prescribed by the medical officer or dietician. [3]

However in the underdeveloped countries, sometimes the nurse may insert NG tube if her nursing diagnoses make provision especially in the absence of a medical doctor.

Nasogastric intubation which is an advanced nursing procedure is used for feeding, administration of medication and laboratory diagnoses. [1, 4] It is vital that nurses inserting them know the correct insertion technique care and as well as procedure for verifying their correct positioning, hence to successfully carry out this procedure the nurse should have in possession the certificate of S. R. N., BSc. and Masters in Nursing. [4, 5] Historically, it seems using tubes for feeding patients goes back at 3500 years to ancient Greek and Egyptian civilizations. [5]

Papyrus evidences suggested that Egyptian physicians

used reeds and animal bladders to rectally feed patient things like wine, milk, whisky, broth and so on to treat a range of complaints. [6]

Capivaceus in 1598, used a hollow tube with a bladder attached to one end, filled with some form of nutrient solution, down as far as a patient's esophagus. [7, 8] The beautifully named Agvapendente used a form of nasopharyngeal tube in 1617, the forerunner of NG tubes, but only going as far as the pharynx. [7, 8]

Theoretically, according to the United States Conference of Catholic Bishops in 2001, they state "there should be a presumption in favour of providing nutrition and hydration to all patients including patients who require medically assisted nutrition and hydration as long as this is of sufficient benefit to outweigh the burden involves to the patient. [9-11] On March 20th 2014, Pope John Paul II addressed participants at a four-day conference sponsored by the Pontifical Academy for Life and the International Federation of Catholic Medical Associations. [10, 11] He addressed the issue of artificial hydration and nutrition in patient, he said, "if patients are not dying, artificial nutrition in principle, ordinary and proportionate and as such, morally obligatory, in so far as and until it seen to have attained its proper finality, which in the present consist in providing nourishment to the patient and alleviation of his suffering. [9-11]

From the conceptual aspect, patients who are unable to eat or drink, NG intubation and feeding is one way to ensure patient received adequate nutrition and medication. [10] Also, NG intubation is a less invasive alternative to surgery in the event, an intestinal obstruction can be removed easily without surgery. [1] Despite some disadvantages associated with NG tube, a child can do well with NG tube for several years. [4, 5, 7]

Nasogastric tubes are widely used in the world's hospital, yet in spite of the fear campaigning to expose the dangers, still patient are dying from the complication of wrong insertion, further clinical research is needed in this care, but small studies suggested that magnet-tracking devices where a magnet is inserted into the tip may hold promise for the future.² The modern soft and atraumatic NG tubes are made up of polyurethane which becomes more soft on exposure to patient's body temperature. [1, 2]

Also the National Patient Safety, made some recommendations stating that individual risk assessment should be carried out prior to nasogastric tube feeding. [3, 4, 6] The absences of respiratory distress should not be interpreted for correct placement and acidity/alkalinity should not be tested using blue litmus paper, while "whoosh" test should be cease immediately. [8]

Nurses seem to be scared in caring for NG Tube patients while some nurses seem not to be aware of the of the patients needs with an NG Tube and the specific care required. [1, 4] This is why the researcher thought it wise to research on this topic so as to close the gaps and fear associated with NG Intubation.

Some research questions where:

- i. Do Nurses at the Laquintinie Hospital Douala know the

indications for Nasogastric Intubation?

- ii. Do Nurses at the Laquintinie Hospital Douala know the nursing interventions being given to a patient with nasogastric tube?
- iii. What challenges do the nurses at the Laquintinie hospital Douala face in the care of patient with NG tubes?

Some objectives for these study where: To assess approaches used by the nurses at the Laquintinie hospital Douala in the care of patient with NG tubes.

- i). To investigate the indications of nasogastric intubation.
- ii). To identify nursing interventions being given to a patient with a nasogastric tube.
- iii). To identify the challenges, face by nurses face when caring for a patients with NG tubes.

The importance of this study is to raise awareness on the importance of care given to patients with NG Tubes and how it could prevent some complications and promote recovery hence limiting patients stay in the hospital.

This study is titled "Approaches Nurses used in the care of patients with nasogastric tubes at the Laquintinie hospital Douala which was conducted from April 19th to June 18th 2016.

During the study, there were a number of limitations that were posed which include:

- Some of the nurses refused to answer the questions that were posed in the interview guide, since it was optional, they claim they were busy and had been out of school for a long time.
- More so, method of communication was a problem, as some claimed not to understand English language at all.
- The length of time used to approve administrative clearance was also a problem, since the general supervisor found it difficult to approve administrative clearance on time.
- Despite the difficulties encountered sufficient data was obtained and hence made a production of this work a reality.

2. Methods and Materials

2.1. Study Design and Duration

A Hospital based descriptive cross-sectional study employing both interview and observation. The study design was done to determine the "Approaches used by nurses in the care of patient with nasogastric tubes". This study necessitated sampling the opinion of the respondent in relation to variables under investigation.

The study lasted for 2 months.

2.2. Definition of Terms

Nasogastric Intubation: Is a tube design to access the stomach through the nose, nasopharynx and esophagus for examination, treatment or other purposes.

- Nursing: Is a helping and independent profession that provides services that contribute to the health of the people.

- Catheter: A Flexible tube for insertion into a narrow opening so that fluid may be introduced or removed.

2.3. Study Area

This study was carried out at the Laquintinie Hospital Douala (LHD). Douala which is located at the Littoral region of Cameroon, it is the economic capital of Cameroon that is, it is based on commercial and industrial activities, since most of the home industries are found in Douala. The L.H.D is or reference hospital situated in the heart of Bonako quarter (Akwa). It is bounded at the North by “La Palais Dika Akwa”, at the South by the Ngodi cemetery, in the West by La Salle des Fetes d’Akwa” and the East by the Akwa polyclinic. The Laquintinie hospital Douala has many building about 38 pavilions an external consultation block and 600 employed people with a capacity of 710 beds.

It is made up of the following units:

- Medical unit divided into: Enterogastrology unit, cardiology, medical A and B
- Paediatric unit which is divided into: paediatric. A stage, paediatric B, paediatric Reanimation neonatal section.
- Maternity unit which is divided into: the labour room, maternity A. B, C, D, E and G sector for premature babies.
- The surgical unit which is divided into: surgical A, B, C and D.
- Psychiatric unit.
- Others includes: the emergency department, pharmacy, laboratory, ultrasound, and x-ray room economic, the central administration and mortuary.

2.4. Study Population

This study comprises of nurses and ward charges of all age group, level of training and working experiences, who were willing to participate in the study.

2.5. Sample Size and Sampling Technique

The sample size consists of 20 nurses including ward charges, convenient sampling technique was used, and the targeted population was made up of nurses who work in the paediatric, medical intensive care unit and surgical unit with different level of training and working experiences.

2.6. Inclusion Criteria

This study includes all the nurses in the Laquintinie hospital Douala who work in the paediatric, medical intensive care unit and surgical unit.

2.7. Exclusion Criteria

Those who were excluded in this study were: medical doctors, lab technicians, nurses who have never carried out NG intubation, student doctors and student nurses.

2.8. Research Instrument

A well structured interview and observational guide was

designed base on the objectives. Also, pen, pencil, ruler and papers were used. In order to ease understanding, libraries, internets, websites were all used.

2.9. Authorisation and Ethical Consideration

An authorization was obtained that is a consent form, from the administration of St. Francis Higher Institute of Nursing and Midwifery in Buea, which was submitted to the General Supervisor of Laquintinie Hospital Douala. After a careful examination this was approved and we were directed on how to go about. All information were kept confidential and the importance of the research were explained to nurses involve in the study.

2.10. Data Analysis

The data generated from the study was entered into a Microsoft Excel page the data was analyzed using tables to ease understanding of the data. Sampling was carried out through purposeful random sampling where any nurse who was willing to participate was included in the study.

3. Results

3.1. Demographic Data

A total of 20 nurses of age range 30 and above were involved in the study carried out at the Laquintinie Hospital Douala from April to June.

From the data collected all the 20 (100%), nurses were female and Christians with different working experiences of 3-5 years 12(60%), and 6-10 years, 8 (40%), as shown in table 1 these nurses also presented with different qualifications, 5 (25%), were nursing assistants, 11 (55%), were SRN, 1 (5%) is HND, 2 (10%), were BSc and 1 (5%), were masters holders.

Table 1. Distribution of Respondents by Age, working experience and Qualification.

Factor	Category	Frequency	Percentage
Age	30-35	10	50%
	36-40	10	50%
Working experience	3-5 years	12	60%
	6-10 years	8	40%
qualification	Nursing assistant	5	25%
	SRN	11	55%
	HND	1	5%
	BSc	2	10%
	Masters holders	1	5%

Table 2. Distribution of Respondents' Religion.

Religion	Frequency	Percentage
Christians	35	70%
Muslims	10	20%
Others	5	10%
Total	50	100%

With regards to religion majority, 35 (70%) of respondents were Christians, 10 (20%) were Muslims and 5 (10%)

belonged to others.

3.2. Nurses Knowledge on the Indications of N. G Tube

Table 3. Nurses response on what are the indications of N. G. tube.

Factor	Frequency	Percentage
Drug administration	20	40%
treatment of ileus bowel or obstruction	25	50%
For enteral feeding	5	10%
Total	50	100%

The result presented in table3 shows that, 20 (40%) of respondents gave drug administration as an indication for N.G tube, 25 (50%) said for treatment of ileus and 5 (10%) said for enteral feeding.

Table 4. Nurses' response on what are the contra indications of N. G intubation.

Factor	Frequency	Percentage
severe mid face trauma	12	60%
Recent nasal surgery	5	25%
excessive manipulation during placement	3	15%
Total	20	100%

As represented on table 4: 12 (60%) of the respondents were of the opinion that severe mid face trauma is contraindicated for intubation, 5 (25%) said recent nasal surgery and 3 (15%) also said patients in coma are contraindicated.

Table 5. Nurses response on the complications of N. G intubation.

Factor	Frequency	Percentage
Diarrhoea	37	74%
Nausea and vomiting	10	20%
Aspiration of food contents	3	6%
Total	50	100%

As represented on table 5; 37 (74%) knew diarrheal as a complication for N. G intubation, 10 (20%) said nausea and vomiting and 3 (6%) gave aspiration of food as one of the complications of N. G intubation.

Table 6. Nurses response on the nursing intervention of patients with N.G intubation.

Factor	Frequency	Percentage
Explain procedure to the patient	30	60%
Set up iv line	15	30%
Examine the nostrils for deformity	5	10%
Total	50	100%

From the data collected; 30 (60%) of the respondents say explain procedure to the patient, 15 (30%) were of the opinion that set up IV line and 5 (10%) said examine the nostrils for deformity.

Table 7. nurses response on nursing intervention before the procedure.

Factor	Frequency	Percentage
Informed consent	40	80%
Ask if any allergies	9	18%
Any nose surgery	1	2%
Total	50	100%

From the data collected; 40 (80%) of the respondents were

of the opinion that informed consent should be obtained, 9 (18%) knew that they should ask of any allergies and 1 (2%) said they will ask if any nose surgery before the procedure.

Table 8. Nurses response on nursing intervention after the procedure.

Factor	Frequency	Percentage
Monitor input and output	22	44%
Skin and abdomen	26	52%
Vital signs	2	4%
Total	50	100%

With regards to table 7; 22 (44%) said monitor input and output, 26 (52%) said skin and abdomen and 2 (4%) also said vital signs monitor are nursing interventions after the procedure.

3.3. Nurses Knowledge on the Challenges Faced When Caring for a Patient with N. G tube

Table 9. Nurses' response on challenges faced in the care.

Factor	Frequency	Percentage
Challenges from patients refusal	20	40%
Challenges by refusal of members	15	30%
Challenges from block tube and patients refusal	15	30%
Total	50	100%

From the data collected: 20 (40%) of the nurses faced challenges from patients refusal 15 (30%) faced challenges from family members refusal and 15(30%) of the nurses had challenges from blocked tubes and patient refusal.

Table 10. Nurses' response on solutions that were implemented.

Factor	Frequency	Percentage
Patients and family members were given health education on the importance of the procedure	35	70%
Blocked tubes were removed and the importance of the procedure emphasized	15	30%
Total	50	100%

From the data collected, all the 35 (70%) nurses who had challenges implemented health education on the importance of the procedure to the patients and family members as a solution to the challenges faced from patient's and family members refusal,15(30%) of the nurses removed blocked tubes and the importance of the procedure emphasized.

4. Discussion

4.1. Nurses Knowledge on the Indications of N. G tube

From the results above it could be seen that 20 (40%) of the nurses knew drug administration as an indication of N. G. tube, 25 (50%) said treatment of ileus or bowel obstruction is another indication of .N. G tube which is in accordance with who stated that gastro intestinal decompression using nasogastric tube is important for the treatment of patients with bowel obstruction or prolonged ileus while 5 (10%) of the nurses gave enteral feeding as another indication of nasogastric intubation as seen in table 3. [12]

Based on the contraindications of nasogastric intubations, 12 (60%) of the nurses knew the different contraindication of nasogastric intubation as they stated that severe mild face trauma is contraindicated for nasogastric intubation, 5 (25%) gave recent nasal surgery as another contraindications for nasogastric intubation also, 3 (15%) of nurses saw excessive manipulation during placement as a contraindication for nasogastric intubation which is in line with Dourgault and Bercik, which stated that excessive manipulation or movement by the patient during placement including coughing as seen in table 4. [10, 11]

With regards to the complications of nasogastric intubation, 37 (74%) of nurses knew diarrheal as a complication for nasogastric intubation as 10 (20%) of the nurses gave nausea and vomiting as another complication of nasogastric intubation and 3 (6%) of the nurses said aspiration of food contents is also a complication of nasogastric intubation which is in line with Stock, which stated that diarrheal nausea and vomiting, aspiration of food are complication of nasogastric intubation. [13] As seen in table 5.

4.2. Nurses Knowledge on the Intervention on Patients with Nasogastric Intubation

As represented on nursing intervention on patients with nasogastric intubation 30 (60%) of the nurses explain procedure to the patient, 15 (30%) of the nurses set up iv line and 5 (10%) of the nurses examine the nostrils for deformity which are nursing interventions of patients with nasogastric intubation which is in line with Stock, Broke, Smeltszer, which stated that explain the procedure, benefit, risk, complication and also examine the patients nostrils for septal deviation. [13-15]

Also, nurses knowledge on the nursing intervention before the procedure, 40 (80%) of the nurses signed informed consent before the procedure as 9 (18%) of the nurses ask the patient if any allergies before the procedure and 1 (2%) of the nurses ask if any surgery before the procedure which is in line with Grol. [12]

Based on nurses knowledge on nursing intervention after the procedure, 22 (44%) of the nurses gave monitoring input and output as an intervention after the procedure, 26 (52%) said monitor skin and abdomen and 2 (4%) also said that vital signs monitor after the procedure which is in line with Merck Manual of diagnosis and therapy, which says that, the nurse will keep track of the amount of liquid the patient takes in, and the amount he sends out by measuring the amount of urine out. [1, 2] The nurse should check for blood pressure, heart rate, breathing rate and temperature, they should also ask about pain.

4.3. Challenges Faced by Patients in the Care of Patients with N. G tube

According to the data collected, 20 (40%) nurses who had carried out N. G intubation on patient faced challenges, 15 (30%) nurses had challenges by family members refusal and 15 (30%) nurses had had challenges from blocked tube and

patient refusal.

Also, with regard to these challenges faced, some solutions were given as 35 (70%) nurses gave health-education to patients and family members 15 (30%) nurses removed block tubes and the importance of the procedure emphasized.

5. Conclusion

Based on the data collected and careful analysis of data, it can be concluded that:

- i). Majority of the nurses at the Laquintinie hospital Douala knows the indications of nasogastric
- ii). Intubations.
- iii). Nurses at the Laquintinie hospital Douala know the nursing interventions given to a patient with NG tube.
- iv). The nurses at the Laquintinie hospital Douala faces some challenges in the care of patients with NG tubes such as patient and family member refused and block tubes.

Recommendation

Based on the analysis of data collected and careful examination of the result the following recommendations were made:

- i). The nurses at the L. H. D should attend seminars on the different strategies used in the care of patients with NG tubes.
- ii). The nurse should also go in for more research on internet, textbooks and journals.
