Effect of Combination of Acapella Device and Breathing Exercises on Treatment of Pulmonary Complications After Upper Abdominal Surgeries. *Journal of Surgery*. Special Issue: Gastrointestinal Surgery: Recent Trends. Vol. 4, No. 2-1, 2016, pp. 10-14. doi: 10.11648/j.js.s.2016040201.13

Abstract: *Introduction: Background.* Upper abdominal surgery alters postoperative pulmonary function, as observed by impairment of lung volumes such as total lung capacity, vital capacity. Impaired clearance of sputum results in a vicious cycle of colonization and infection of bronchi with pathogenic organisms, dilation of bronchi and further production of sputum. *The aim* was to investigate the effect of combination of Acapella device and breathing exercises on treatment of post operative pulmonary complications after upper abdominal surgeries. *Subjects and methods:* Sixty patients underwent upper abdominal surgery were assigned randomly into two equal groups; their ages ranged from 20-50 years. The study group received breathing exercises, Acapella device and traditional chest physical therapy program (postural drainage, percussion, vibration, cough training and early ambulation). Control group received traditional chest physical therapy program (postural drainage, percussion, vibration, cough training and early ambulation). All groups received three sessions per week for four successful weeks. The data were collected before and after the same period of treatment for both groups. Evaluation procedures were carried out to measure pulmonary function: Forced vital capacity (FVC) and Forced expiratory volume in one second (FEV1) using electronic spirometer. *Results:* Post treatment results showed that there was a significant improvement difference in FVC and FEV1 in both groups in favor of the study group. Percentage of improvement of FVC in the study group was 42.28%, while it was 16.31% in the control group. Percentage of improvement of FEV1 in the study group was 49.05%, while it was 20.79% in the control group. *Conclusion:* Combination of Acapella device and breathing exercises were considered to be an effective modality for treatment of postoperative pulmonary complications and removal of secretions after upper abdominal surgeries.

Keywords: Acapella Device, Breathing Exercises, Pulmonary Complications, Spirometer, Upper Abdominal Surgeries

1. Introduction

Patients submitted to upper abdominal surgery (UAS) usually develop a restrictive lung pattern, with changes to pulmonary mechanics in the first post operative days. This can cause a reduction in inspiratory capacity, total inspiratory time, and ventilation at the lung bases, leading to a high risk of developing post operative pulmonary complications (PPCs) [1]. For adequate pulmonary ventilation to occur, it is fundamental that the forces that act on the respiratory system favor the thoracic and abdominal movements, especially the respiratory muscle strength that is compromised after UAS [2].

A major decline in pulmonary function [Forced vital capacity (FVC) and Forced expiratory volume in one second (FEV1)] is observed on the first day after upper abdominal surgery. This decline can reduce vital and inspiratory capacity and can culminate in restrictive lung diseases that cause atelectasis, reduced diaphragm movement, and respiratory insufficiency [3].

PPC defined as new onset or exacerbation of respiratory failure following surgery, occur frequently [4]. A thorough understanding of the clinical effects of PPC is hindered by inconsistency in the definition of PPC among researchers. The diagnoses classically considered PPC including atelectasis, bronchospasm, pneumonia, pulmonary edema,

and respiratory failure. Respiratory failure itself is not clearly defined, although the most common criterion is failure to be extubated within 48 hours of surgery [5].

Airway secretions, particularly those in peripheral airways, require a forced expiratory maneuver for expectoration. To facilitate passage of air to alveoli beyond the secretions, a deep breathing maneuver is adopted prior to the application of forced expiratory techniques [6].

The Acapella (Smiths Medical Inc, Carlsbad, California, USA) is a handheld airway clearance device that operates on the same principle as the Flutter, i.e. a valve interrupting expiratory flow generating oscillating PEP. Utilizing a counterweighted plug and magnet to achieve valve closure, the Acapella is not gravity dependent like the Flutter. The Acapella comes in three models, a low flow (<15 L/min), high flow (>15 L/min) and the Acapella Choice. The high and low flow models have a dial to set expiratory resistance while the Choice model has a numeric dial to adjust frequency [7].

Oscillating devices such as the flutter and acapella have a twofold effect on secretion clearance. Oscillation has been shown to decrease the viscoelastic properties of mucus hence making it easier to mobilize up the airways. The second effect of the oscillations is to cause short bursts of increased acceleration of the expiratory airflow which assist in mobilizing the secretions up the airways [8].

The aim of this study was to investigate the effect of combination of Acapella device and breathing exercises in treatment of post operative pulmonary complications after upper abdominal surgeries.

2. Subjects, Materials and Methods

This study was carried out on 60 adult patients of both sexes suffering from pulmonary complications and accumulation of secretions after upper abdominal surgery, their ages ranged from 20 to 50 years and selected from general surgery department at Om El Masryeen Hospital, Giza, Egypt during the period of February 2015 to August 2015. Patients were randomly assigned into two equal groups; Group A (Study group) and Group B (Control group). Group A received deep breathing exercises, Acapella device and traditional chest physical therapy program (postural drainage, percussion, vibration, cough training and early ambulation) and group B received traditional chest physical therapy program (Postural drainage, percussion, vibration, cough training and early ambulation).

Patients with the following conditions were excluded from the study; malignant disease, infection, active inflammation or sepsis. Patients spent more than 48 hours on mechanical ventilation, Instability of patient's medical condition, heavy smokers, alcohol drinking and patient with any spirometry contra-indications (e.g. Unstable cardiovascular status, pneumothorax, active hemoptysis and abdominal or cerebral aneurysms) were also excluded.

The work has been carried out in accordance with the ethics of committee for experiments at Faculty of Physical

Therapy, Cairo University involving humans, and parents filled approval consent to share in the study.

The assessment approach was: Spirometer which is a computerized instrument that records: forced vital capacity (FVC) and forced expiratory volume in the first second (FEV1) at the beginning of the study (1st day post operative) and after four successive weeks.

Preparation of Acapella device: The Acapella adjustment frequency dial turned counterclockwise to lowest resistance setting. As the patient improve, adjust proper resistance upward by turn the dial clockwise, the patient instructed to: 1- Sit in a comfortable position. 2- Take in breath that larger than normal but not to fill the lungs completely. 3- Position the mouthpiece maintaining a tight seal with his lips. 4- Hold breath for 2 or 3 sec. 5- Try not to cough and exhale slowly for 2 to 3 sec through the device while it vibrates. 6- Remove the mouthpiece and cough or "huff cough". To huff cough, take a deep breath. Hold it for 1-3 seconds. Then, force air out of his lungs with his mouth open like he would do if he were trying to fog a mirror. 7- Continue breathing with the Acapella with breaks to cough about every 5 minutes for a total treatment time of 20 – 30 minutes [9].

Statistical Analysis

Descriptive statistics and T- test for comparison of the mean age of both groups. Independent T-test for comparison of FVC and FEV1 between both groups. Paired T-test for comparison between pre and post treatment mean values of FVC and FEV1 in each group. The level of significance for all statistical tests was set at $p < 0.05$. All statistical tests were performed through the statistical package for social studies. (SPSS) version 19 for windows (IBM SPSS, Chicago, IL, USA).

3. Results

The statistical analysis for patient's socio-demographic data (age, sex) revealed a non significant difference between both groups.

Results revealed that; There was no significant difference in mean values of FVC between both groups pre treatment ($p = 0.26$). While there was a significant increase in FVC in group A post treatment compared to that of group B ($p = 0.0001$) as shown in table 1 and figure 1.

There was no significant difference in mean values of FEV1 between both groups pre treatment ($p = 0.41$). While there was a significant increase in FEV1 in group A post treatment compared to that of group B ($p = 0.0001$) as shown in table 2 and figure 2.

Table 1. Pre and post treatment results of FVC for both groups.

	Pre treatment		Post-treatment	
	Group A	Group B	Group A	Group B
X	1.49	1.41	2.12	1.64
SD±	± 0.23	± 0.26	± 0.33	± 0.32
t- value	1.13		5.61	
p- value	0.26		0.0001	
Significance	Non significant		Significant	

Table 2. Pre and post treatment results of FEV1 for both groups.

	Pre treatment		Post-treatment	
	Group A	Group B	Group A	Group B
X	1.06	1.01	1.58	1.22
SD±	± 0.16	± 0.22	± 0.24	± 0.24
t- value	0.83		5.55	
p- value	0.41		0.0001	
Significance	Non significant		Significant

Figure 1. Pre and Post-treatment mean values of FVC (L) for both groups. **Figure 2.** Pre and Post-treatment mean values of FEV1 (L) for both groups.

Statistical analysis of results showed a significant improvement in FVC and FEV1 in group A and group B after 4 weeks of treatment as follows:

Results of FVC: The mean $\pm$ SD pre treatment of group A was 1.49 ± 0.23 L and that post treatment was 2.12 ± 0.33 L. The mean difference was -0.63 L and the percent of improvement was 42.28%. There was a significant increase in mean value of FVC post treatment compared with pre treatment in group A ($p = 0.0001$). While in group B the mean $\pm$ SD of FVC pre treatment was 1.41 ± 0.26 L and that post treatment was 1.64 ± 0.32 L. The mean difference was -0.23 L and the percent of improvement was 16.31%. There was a significant increase in mean value of FVC post treatment compared with pre treatment in group B ($p = 0.0001$) as shown in table 3 and figure 3.

Results of FEV1: The mean $\pm$ SD pre treatment of group A was 1.06 ± 0.16 L and that post treatment was 1.58 ± 0.24 L. The mean difference was -0.52 L and the percent of improvement was 49.05%. There was a significant increase in mean value of FEV1 post treatment compared with pre

treatment in group A ($p = 0.0001$). While in group B the mean $\pm$ SD of FEV1 pre treatment was 1.01 ± 0.22 L and that post treatment was 1.22 ± 0.24 L. The mean difference was -0.21 L and the percent of improvement was 20.79%. There was a significant increase in mean value of FEV1 post treatment compared with pre treatment in group B ($p = 0.0001$) as shown in table 4 and figure 4.

Table 3. Pre and post treatment results of FVC for each group.

	Group A		Group B	
	Pre	Post	Pre	Post
X	1.49	2.12	1.41	1.64

5. Discussion

The findings of this study indicated that patients suffering from pulmonary complications following upper abdominal surgery had a significant improvement in FVC and FEV1 after application of Acapella device with breathing exercises. The statistical analysis revealed a significant improvement of FVC in the study group than that of the control group; the percentage of improvement was 42.28% and 16.31% for the two groups respectively. Also there is a significant improvement of FEV1 in the study group than that of the control group; the percentage of improvement was 49.05% and 20.79% for the two groups respectively.

These results are consistent with authors who supported that combination of Acapella device and breathing exercises is an effective modality in improving pulmonary function and reducing sputum after upper abdominal surgery as follows: after the use of oscillatory positive expiratory pressure (OPEP) there was a statistically significant ($p < 0.05$) improvement in FEV1 23% and FVC 43% compared to baseline with combined bronchodilator therapy. As the OPEP devices have shown a significant increase in lung function parameters (FVC, FEV1 and forced expiratory flow) after more prolonged use in an outpatient setting [10].

The Acapella device characterization showed an oscillation frequency varying from 8 Hz to 21 Hz, mean pressure ranging from 3 cm H₂O to 23 cm H₂O, and oscillation amplitude from 4 cm H₂O to 9 cm H₂O. These parameters increased with flow and instrument adjustment [11]. The Acapella devices elicit higher vibration amplitudes (5 to 8 cmH₂O) than the water bottle (1.8 cmH₂O). The Acapella devices may be more efficient for secretion mobilization than the water bottle, because they elicit greater amplitude of vibrations [12].

The OPEP provides an improvement both in pulmonary function tests (FVC, FEV1) and quality of life. This treatment should be included among the principal options in chest physiotherapy [13]. There was a significant improvement of FVC and FEV1 also arterial oxygen pressure (PaO₂), carbon dioxide pressure (PaCO₂) improved after 4 weeks in patients with chronic obstructive pulmonary diseases (COPD) after upper abdominal surgery [14].

Breathing exercises with positive expiratory pressure (PEP) are commonly recommended for the prevention of pulmonary complications after abdominal surgery. Scientific documentation of the effects of PEP treatment is limited. In total, 24 (54%) of the physical therapists answered the questionnaire. All reported using breathing exercises with PEP as a treatment option after abdominal surgery [15].

Application of Acapella device for chest physiotherapy when compared with multimodality chest physiotherapy resulted in significant increase in the mean values of sputum amount, significant decrease in sputum viscosity, improved radiological signs of atelectasis, shorter duration of ventilator support, and less ICU stay. So, Acapella device is a good representative to all conventional multi-modality chest physiotherapy procedures with high success rate and can

replace the exhausting, costly, and time consuming conventional procedures in COPD patients [16].

Positive expiratory pressure technique provides a significantly greater improvement in the pulmonary function when compared to postural drainage with percussion. Other procedures are also utilized such as the Flutter device, autogenic drainage, the positive expiratory pressure technique, forced expiration techniques and intrapulmonary percussive ventilation [17].

Pulmonary function tests: forced vital capacity (FVC), forced expiratory volume in the first second (FEV1), FEV1/FVC ratio, peak expiratory flow (PEF) and diaphragm excursion values between preoperative and postoperative (first, second) days were found to be higher in the exercise group diaphragmatic breathing exercise, (other therapies like bronchial hygiene therapy, Thoracic mobility exercise and mobilization) when compared to control group performed on twenty sample sizes who underwent laparoscopic surgery [18]. In addition, the effect of breathing exercises during the immediate postoperative period following upper abdominal surgery seem to provide some benefit in improving pulmonary function, reducing pulmonary complications and postoperative hospital stay, as the study group showed significant improvement in FEV1 (21.47%) ($P < 0.001$), FVC (12.96%) ($P < 0.05$) as compared to the control group [19].

In contrast it was found that there were no statistically significant differences among the airway clearance regimens of the active cycle of breathing techniques (ACBT), autogenic drainage (AD), positive expiratory pressure (PEP) and the oscillating PEP devices of the Flutter and RC when used over a period of one year, in the sitting position, by adults with cystic fibrosis. It is likely that to optimize adherence to treatment and consequently improvements in morbidity and mortality, the patient should be involved in the selection of his/her airway clearance regimen [20].

It was found that there was no significant difference between weight of sputum expectorated with ACBT treatment and weight of sputum expectorated with Acapella treatment. The Acapella is as effective method of airway clearance as ACBT and may offer a user-friendly alternative to ACBT for patients with bronchiectasis [21, 22].

From the gained results it could be concluded that combination of breathing exercises and Acapella device had a significant improvement of FVC and FEV1 and decrease of post operative pulmonary complications after upper abdominal surgery.
