Abstract: AIDS is one of the most threatening diseases for human being that is caused by a virus named HIV. Here the reduction of the death rate after infected by AIDS has been discussed. A mathematical model of HIV has been formulated. Then its positivity and boundedness has been investigated. It has been shown that it is possible to minimize the mortality rate by providing the treatment to the HIV infected people. Moreover, the control of the transfer rate from the infected class to the AIDS class reduces the disease rate. The increasing of the transfer rate from the infected class to the treated class also reduces the mortality rate.

Keywords: HIV, AIDS, Reproduction Number, Endemic Equilibrium Point

1. Introduction

In the last decades or so mathematical models in epidemiology are playing a very important role in analyzing the spread and control of the infectious disease that are causing a lot of human death every year. In the past, human being have been threatened by many infectious disease, most of them are caused by viruses [1]. Among them HIV is responsible for a lot of human death. Till now people are dying by this virus.

Human Immunodeficiency Virus (HIV) is a member of Lent Virus sub member family of retrovirus that produces chronic infections in the host and gradually damages the host's immune system [2]. There are two types of HIV viruses: HIV-1 and HIV-2. Among them, HIV-1 is more dangerous. It easily transmits among the people and causes a lot of HIV infections globally every year [3]. Immediately after HIV infection, people cannot determine his/her infection. In this time, HIV infection may not show up on an HIV test, but people who have it are highly infectious and can spread the infection to others. People with chronic HIV infection may not have any HIV-related symptoms or only mild ones [4].

After being infected, people who aren't taking medicine to treat HIV, this period can last a decade or longer, but some

may progress through this phase faster. People who are taking medicine to treat HIV the right way, every day may be in this stage for several decades because treatment helps keep the virus in check.

HIV is treated using a combination of medicines to fight HIV infection. This is called antiretroviral therapy (ART). ART isn't a cure, but it can control the virus so that one can live a longer, healthier life and reduce the risk of transmitting HIV to others. ART is recommended for all people with HIV, regardless of how long they've had the virus or how healthy they are. If left untreated, HIV will attack the immune system and eventually progress to AIDS.

2. Formulation of the Model

The total sexually-active population at time t , denoted by $N(t)$, is subdivided into mutually-exclusive compartments, namely susceptible ($S(t)$), exposed to HIV but show no clinical symptoms of the disease ($E(t)$), HIV infected individuals with clinical symptoms of HIV ($I(t)$), infected individuals who are taking treatment ($T(t)$), individuals having AIDS ($A(t)$), so that

$$N(t) = S(t) + E(t) + I(t) + T(t) + A(t)$$

Let us suppose that the susceptible population is increasing

at a constant rate. Let the rate be Π .

Susceptible individuals acquire HIV infection, following effective contact with people infected with HIV only (i.e. those in the E, I and T classes) at a rate λ , where

$$\lambda = \frac{\beta(E+\theta_1 I+\theta_2 T+\theta_3 A)}{N} \text{ [Force of infection for HIV.]}$$

Here β is the transmission rate for HIV and $\theta_3 > \theta_1 > \theta_2 > 1$ are known as the modification parameter. These modification parameters indicate that the infected individuals are more infectious than the treated class. Among these class, AIDS class is assumed to spread more infection than other two classes. In the HIV exposed class ($E(t)$), individuals entering into this class from susceptible class ($S(t)$) at a rate λ . In the HIV exposed class ($E(t)$) individuals progress to infected class ($I(t)$) at a rate ω . Individual also progresses to the treatment class ($T(t)$) at a rate τ_1 . And Individual also progresses to the AIDS class ($A(t)$) at a rate δ_1 .

In the treatment class, individuals progress to AIDS class ($A(t)$) at a rate τ_3 . Also individuals progress to the AIDS and HIV treatment class ($T(t)$) at a rate τ_4 . In this class, let $(\mu + d)$ denotes the death rate due to the disease and μ be the natural mortality rate.

Combining all the aforementioned assumption and definitions, the model becomes:

$$\begin{aligned} \frac{dS}{dt} &= \pi - \lambda S - \mu S \\ \frac{dE}{dt} &= \lambda S - \omega E - \mu E \\ \frac{dI}{dt} &= \omega E - \tau_1 I - \delta_1 I - \mu I \\ \frac{dT}{dt} &= \tau_1 I + \tau_4 A - \tau_3 T - \mu T \\ \frac{dA}{dt} &= \delta_1 I - \tau_4 A + \tau_3 T - (\mu + d)A \end{aligned} \tag{1}$$

Where, $\theta_3 > \theta_2 > \theta_1 > 1$.

Schematically this can be shown as follows:

Figure 1. Diagram of the model.

3. Analysis of the Model

3.1. Boundedness Region

Here we have used some parameters (explained in the table 2) to described the model (1). These variables are non-negative. Also the state variables (described in table 1) are non-negative for all time $t > 0$.

The total population is denoted by $N(t)$. Total population can be written as:

$$N(t) = S(t) + E(t) + I(t) + T(t) + A(t).$$

The equation written above, is changing at a rate

$$\frac{dN}{dt} = \frac{dS}{dt} + \frac{dE}{dt} + \frac{dI}{dt} + \frac{dT}{dt} + \frac{dA}{dt} = \pi - \mu N - dA \tag{2}$$

In absence of disease, i.e. for $E = I = T = A = 0$, we have

$$\frac{dN}{dt} \leq \pi - \mu N \tag{3}$$

By the separation of variables we can write

$$\frac{dN}{\pi - \mu N} \leq dt$$

After integration we have

$$\pi - \mu N \geq C e^{-\mu t} \tag{4}$$

Here C is the integrating constant which is to be determined. Let at $t = 0, N = N_0$. From the Eq. (4) we have

$$C = \pi - \mu N_0$$

Putting the value of C in Eq. (4) we have

$$\pi - \mu N \geq (\pi - \mu N_0) e^{-\mu t} \tag{5}$$

As $t \rightarrow \infty, 0 \leq N(t) \leq \frac{\pi}{\mu}$

Therefore, the region $\Psi = \{(S, E, I, T, A) \in \mathfrak{R}_+^5 : N \leq \frac{\pi}{\mu}\}$ contains the feasible solution of the model (1).

3.2. Positivity of Solution

Now we need to check the positivity of the solution of the model (1). Let the initial data be $\{S(0), E(0), I(0), T(0), A(0) \in \Psi\}$. Now we have to show that the solution set $\{S(t), E(t), I(t), T(t), A(t)\}$ of the system (1) is positive.

Consider the 1st equation of the model (1)

$$\frac{dS}{dt} = \pi - \lambda S - \mu S > -(\lambda + \mu)S \Rightarrow \frac{dS}{dt} > -(\lambda + \mu)S$$

After integration we can write

$$S(t) > S(0)e^{\int -(\lambda+\mu)dt} > 0 \text{ provided } (\lambda + \mu) < \infty.$$

Similarly from the 2nd, 3rd, 4th and 5th equations respectively we have

$$E(t) > E(0)e^{\int -(\omega+\mu)dt} > 0 \text{ provided } (\omega + \mu) < \infty.$$

$$I(t) > I(0)e^{\int -(\tau_1+\delta_1+\mu)dt} > 0 \text{ provided } (\tau_1 + \delta_1 + \mu) < \infty.$$

$$T(t) > T(0)e^{\int -(\tau_3+\mu)dt} > 0 \text{ provided } (\tau_3 + \mu) < \infty.$$

$$A(t) > A(0)e^{\int -(\tau_4+\mu+d)dt} > 0 \text{ provided } (\tau_4 + \mu + d) < \infty.$$

Thus the solution set $\{S(t), E(t), I(t), T(t), A(t)\}$ is positive for $t > 0$.

4. Disease-Free Equilibrium Point

Disease free equilibrium point is denoted by E_0 . To obtain the disease-free equilibrium points on $\Psi \cap \mathbb{R}_+^5$, we need to put $E = I = T = A = 0$ (since in the disease-free equilibrium there is no disease). The positive DFE for this model is $N = \frac{\pi}{\mu}$. So we can conclude that the model has a disease-free equilibrium point and the disease-free equilibrium point of this model is $E_0 = (\frac{\pi}{\mu}, 0, 0, 0, 0)$.

5. Local Stability of the Disease-Free Equilibrium

The basic reproduction number which is denoted by R_0 plays a vital role in the stability of the model. The number of new infections generated by an infected individual is known

$$R_0 = [\beta (\theta_1 \omega \tau_4 \mu + \theta_1 \omega \mu \tau_3 + \theta_1 \omega d \mu + \theta_1 \omega d \tau_3 + \theta_2 \omega \tau_1 \mu + \theta_2 \omega \tau_1 d + \theta_2 \omega \tau_4 \delta_1 + \theta_2 \omega \tau_4 \tau_1 + \theta_3 \omega \delta_1 \mu + \theta_3 \omega \delta_1 \tau_3 + \theta_3 \omega \tau_3 \tau_1 + \tau_1 \tau_4 \mu + \tau_1 \mu \tau_3 + \tau_1 d \mu + \tau_1 d \tau_3 + \tau_4 \delta_1 \mu + \tau_1 \mu + \delta_1 \mu^2 + \tau_4 \mu^2 + \mu^2 \tau_3 + d \mu^2 + \delta_1 \mu \tau_3 + \delta_1 d \mu + \delta_1 d \tau_3 + \mu d \tau_3 + \theta_1 \omega \mu^2 + \mu^3) / (\tau_1 \omega \tau_4 \mu + \tau_1 \omega \mu \tau_3 + \tau_1 \omega d \mu + \delta_1 \omega \mu^2 + \omega \mu^3 + \tau_1 \mu^3 + \delta_1 \mu^3 + \mu^3 \tau^4 + \mu^3 \tau_3 + \mu^3 d + \tau_1 \omega \mu^2 + \omega \mu^2 \tau^4 + \omega \mu^2 \tau_3 + \omega \mu^2 d + \tau_1 \mu^2 \tau_4 + \tau_1 \mu^2 \tau_3 + \tau_1 \mu^2 d + \delta_1 \mu^2 \tau_4 + \delta_1 \mu^2 \tau_3 + \delta_1 \mu^2 d + \mu^2 d \tau_3 + \mu^4 + \tau_1 \omega d \tau_3 + \delta_1 \omega \tau_4 \mu + \delta_1 \omega \mu \tau_3 + \delta_1 \omega d \mu + \delta_1 \omega d \tau_3 + \omega \mu d \tau_3 + \tau_1 \mu d \tau_3 + \delta_1 \mu d \tau_3)]$$

Lemma [5]. Local stability of the disease-free equilibrium depends on the basic reproduction number. If the basic reproduction number is bigger than one, then disease-free equilibrium point locally asymptotically unstable and if the basic reproduction number is less than one, then it is locally asymptotically unstable.

6. Global Stability of the Disease-Free Equilibrium

Here we have used a technique established by Castillo-Chavez [6] to investigate the global stability of the disease-free equilibrium point. We rewrite the model as:

$$\frac{dX}{dt} = H(X, Z)$$

$$\frac{dZ}{dt} = G(X, Z), G(X, 0) = 0 \tag{6}$$

Where $X = S$ and $Z = (E, I, T, A, .)$. Here the components of $Z \in \mathbb{R}_+^4$ denotes the infected population. The disease free equilibrium is now denoted as:

$$E_0 = (X^*, 0), X^* = \frac{\pi}{\mu}$$

The condition must be met to guarantee a local asymptotic stability:

$$\frac{dX}{dt} = H(X, 0)$$

as the basic reproduction number. The associated nonnegative matrix F for the new infection terms and the non-singular M -matrix, V for the remaining transfer terms are given respectively by

$$F = \begin{pmatrix} \beta & \beta \theta_1 & \beta \theta_2 & \beta \theta_3 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

And V has the following expression

$$V = \begin{pmatrix} \omega + \mu & 0 & 0 & 0 \\ 0 & -\omega + \tau_1 + \delta_1 + \mu & 0 & 0 \\ 0 & -\tau_1 & \mu + \tau_3 & -\tau_4 \\ 0 & \delta_1 & -\tau_3 & \tau_4 + (\mu + d) \end{pmatrix}$$

The basic reproduction number R_0 is the spectral radius of the matrix FV^{-1} . The eigenvalues of the matrix FV^{-1} are

Here, X^* is globally asymptotically stable (GAS).

$$G(X, Z) = PZ - G^*(X, Z), G^*(X, Z) \geq 0 \text{ of } (X, Z) \in \Omega \tag{7}$$

Where $P = D_Z G(X^*, 0)$, is an M -matrix (the off-diagonal elements of P are non-negative) and Ω is the region where the model makes biological sense. If the system satisfies the conditions of then the theorem below holds:

Theorem [5]. The fixed point $E_0 = (X^*, 0)$ is a globally asymptotically stable equilibrium of the system (6) provided that $R_0 < 1$ and the assumptions in (4) are satisfied.

Proof. Form the model system (1) and (6), we have

$$H(X, 0) = (\pi - \mu S)$$

$$G(X, Z) = PZ - G^*(X, Z)$$

Where

$$G^*(X, Z) = \begin{pmatrix} \beta[E + \theta_1 I + \theta_2 T + \theta_3 A] \left[1 - \frac{S}{N}\right] \\ 0 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} G_1^*(X, Z) \\ G_2^*(X, Z) \\ G_3^*(X, Z) \\ G_4^*(X, Z) \end{pmatrix}$$

Here $G_1^* > 0$ & $(G_2^*, G_3^*, G_4^*) = 0$

So the conditions are fulfilled. So E^* is globally asymptotically stable when $R_0 < 1$.

7. Endemic Equilibrium of the Model

We have used a well-known technique known as the Central Manifold Theorem [6] to check the stability of the

endemic equilibrium point of the model. To apply this theorem we make the following change of variables.

Let

$$S = x_1, E = x_2, I = x_3, T = x_4, A = x_5$$

$$N = x_1 + x_2 + x_3 + x_4 + x_5$$

The model (1) can be rewritten in the form:

$$\frac{dS}{dt} = f(x)$$

Where $X = (x_1, x_2, x_3, x_4, x_5)$, and $F = (f_1, f_2, f_3, f_4, f_5)$, as

$$f_1 = \pi - \lambda x_1 - \mu x_1$$

$$f_2 = \lambda x_1 - \omega x_2 - \mu x_2$$

$$f_3 = \omega x_2 - \tau_1 x_3 - \delta_1 x_3 - \mu x_3$$

$$f_4 = \tau_1 x_3 + \tau_4 x_5 - \tau_3 x_4 - \mu x_4$$

$$f_5 = \delta_1 x_3 - \tau_4 x_5 + \tau_3 x_4 - (\mu + d)x_5$$
(8)

Where $\lambda = \frac{\beta(x_2 + \theta_1 x_3 + \theta_2 x_4 + \theta_3 x_5)}{x_1 + x_2 + x_3 + x_4 + x_5}$

The Jacobean of the system (8) is

$$J = \begin{bmatrix} -\mu & -\beta & -\beta\theta_1 & -\beta\theta_2 & -\beta\theta_3 \\ 0 & -\beta - \mu - \omega & \beta\theta_1 & \beta\theta_2 & \beta\theta_3 \\ 0 & \omega & -\tau_1 - \delta_1 - \mu & 0 & 0 \\ 0 & 0 & \tau_1 & -\tau_3 - \mu & \tau_4 \\ 0 & 0 & \delta_1 & \tau_3 & -\tau_4 - \mu - d \end{bmatrix}$$

To analyze the dynamics of (8), we compute the eigenvalues of the Jacobian of (8) at the disease free equilibrium (DFE). It can be shown that this Jacobian has a right eigenvector given by:

$$V = (V_1, V_2, V_3, V_4, V_5)^T$$

Where

$$V_1 = -\frac{\beta(V_2 + \theta_1 V_3 + \theta_2 V_4 + \theta_3 V_5)}{\mu}$$

$$V_2 = \frac{(\tau_1 + \delta_1 + \mu)V_3}{\omega}$$

$$V_3 = V_3$$

$$V_4 = \frac{\tau_1 V_3 + \tau_4 V_5}{\tau_3 + \mu}$$

$$V_5 = \frac{\delta_1 V_3 + \tau_3 V_4}{\tau_4 + \mu + d}$$

And the left eigenvectors are given by

$$W = (w_1, w_2, w_3, w_4, w_5)^T$$

$$W_1 = 0$$

$$W_2 = \frac{\omega W_3}{\mu + \omega - \beta}$$

$$W_3 = W_3$$

$$W_4 = \frac{\tau_3 W_5 (\beta - \omega - \mu) - \beta \omega \theta_2 W_3}{(\tau_3 + \mu)(\beta - \omega - \mu)}$$

$$W_5 = \frac{\beta \theta_3 W_2 + \tau_4 W_4}{\tau_4 + \mu + d}$$

It can be shown after some manipulations involving the evaluation of the associated non-vanishing partial derivatives of f that

$$S^* = \frac{2\beta}{N} (W_2 + W_3 + W_4 + W_5)(W_2 + W_4\theta_2 + W_5\theta_3 + W_3\theta_1)(V_1 - V_2)$$

And $r^* = -(W_2 + W_4\theta_2 + W_5\theta_3 + W_3\theta_1)(V_1 - V_2)$

Since $v_1 = -\frac{\beta(v_2 + \theta_1 v_3 + \theta_2 v_4 + \theta_3 v_5)}{\mu}$ which is less than zero

and $v_2 = \frac{(\tau_1 + \delta_1 + \mu)v_3}{\omega}$ which is positive.

So $v_1 - v_2 < 0$.

Thus we have

$$S^* = \frac{2\beta}{N} (w_2 + w_3 + w_4 + w_5)(w_2 + w\theta_2 + w_5\theta_3 + w_3\theta_1)(v_1 - v_2) < 0$$

Again w_1, w_2, w_3, w_4, w_5 are all positive and all the parameters are positive. So

$$r^* = -(w_2 + w_4\theta_2 + w_5\theta_3 + w_3\theta_1)(v_1 - v_2) > 0$$

Thus we have established the following theorem:

Theorem. Thus we have the following results: the endemic equilibrium point is locally stable when the basic reproduction number is bigger than one and unstable when basic reproduction number is less than one.

8. Numerical Simulations and Discussions

The description of the variable is shown in the Table 1. In the model we have used some parameters. The values of the parameters that are used in the model are shown in the table 2.

Table 1. Description of variables of the model.

Variables	Descriptions
$S(t)$	Susceptible class
$E(t)$	Individuals Exposed to AIDS but show no clinical symptoms.
$I(t)$	Individuals infected with AIDS not yet displaying symptoms.
$T(t)$	HIV infected individuals are in Treatment Class
$A(t)$	HIV infected individuals and displaying symptoms of AIDS.

Table 2. The values of the parameters of the model.

Variables	Description	Values
Π	Recruitment rate of humans	0.00384 [11]
β	Modification Parameter	0.0082

Variables	Description	Values
θ_1	Modification Parameter	1.2
θ_2	Modification Parameter	1.4
θ_3	Modification Parameter	1.5
δ_1	Transfer rate from $I(t)$ to $A(t)$	0.025[6]
ω	Transfer rate from $E(t)$ to $I(t)$	0.03[8]
τ_1	Transfer rate from $I(t)$ to $T(t)$	0.04[4]
τ_3	Transfer rate from $T(t)$ to $A(t)$	0.025[4]
τ_4	Transfer rate from $A(t)$ to $T(t)$	0.02[5]
μ	Natural Death	0.0003[11]
d	Death rate after having AIDS	0.003[11]

Figure 2 shows that the total infected population is increasing when the basic reproduction number $R_0 > 1$ and figure 3 shows that the infected population is decreasing when $R_0 < 1$. Here the value of the basic reproduction number R_0 depends on the transfer rate τ_1 from the infected class $I(t)$ to treated class $T(t)$. The values of the reproduction number R_0 decreases with the transfer rate τ_1 . Thus we can minimize the mortality rate by increasing the number of the treated population. Figure 4 shows that, the prevalence is decreasing when the basic reproduction number $R_0 < 1$ and figure 5 shows that it is increasing when $R_0 > 1$.

Figure 2. Total infection when $R_0 > 1$.

Figure 3. Total Infection when $R_0 < 1$.

Figure 4. Prevalence when $R_0 < 1$.

Figure 5. Prevalence when $R_0 > 1$.

9. Conclusions

AIDS is one of the devastating diseases for human being. Mathematical models are used to estimate the dynamics of the diseases. Here we have formulated a model describing the HIV with treatment. The findings of the study are listed below:

- We can minimize the mortality rate by providing the treatment to the HIV infected people.
- The basic reproduction number highly depends on δ_1 , which is the transfer rate from $I(t)$ to $A(t)$ class. Thus the reduction in the transfer rate from the infected rate $I(t)$ to the AIDS class $A(t)$ will reduce the mortality rate.
- The increasing of the transfer rate τ_1 from the infected class $I(t)$ to the treated class $T(t)$ also reduces the disease burden.
