Abstract: The paper is devoted to the study of optimal control of Quadratic Optimal Control of Fractional stochastic differential Equation with application of Economy Mode with different types of fractional stochastic formula (ITO, Stratonovich), By using the Dynkin formula, Hamilton-Jacobi-Bellman (HJB) equation and the inverse HJB equation are derived. Application is given to a stochastic model in economics.

Keywords: Fractional Stochastic Differential Equations, Dynkine Formula, Hamilton-Jacobi-Bellman Equation

1. Introduction

In the following controlled Fractional stochastic differential equations was introduced
1. $x(t) = x(0) + \int_0^t (H(t)x(t) + M(t)u(t))dt + \int_0^t b(t)dB^H(t)$.
2. $x(t) = x(0) + \int_0^t (H(t)x(t) + M(t)u(t))dt + \int_0^t b(t)dB(t)$.
3. $x(t) = x(0) + \int_0^t (H(t)x(t) + M(t)u(t))dt + \int_0^t b(t)dB(t)$.

where $x(t)$, $t \in [0, T]$, is a given continuous process, $u(t)$ is a control process, $H(t)$ be $n \times n$ matrices, $M(t)$ be $n \times k$ matrices, $b(t)$ be $n \times m$ matrices, the control $u(t)$ be $k \times 1$ vector, $B^H(t)$ and $B(t)$ are Fractional Brownian Motion and Brownian Motion respectively.

we presented Dynkin formula, This result can be obtained from Taylor formula for above Fractional stochastic differential equations and there generators. By using Dynkin formula and the property of expectation, the Hamilton-Jacobi-Bellman (HJB) equation and the inverse HJB equation have been stated. The stochastic optimal control for the fractional stochastic delay equation was found in the paper [1], we will give the proof for Dynkin formula, the Hamilton-Jacobi-Bellman (HJB) equation, the inverse HJB equation and the optimal control for each of the above equation. For a definitions related to optimal control see [2], a Ramsey model [4, 6] that takes into account the randomness in the production cycle.

The models is described by the equations
1. $dk(t) = [H(t)k(t) + u(k(t))]dt + b(k(t))dB^H(t)$
2. $dk(t) = [H(t)k(t) + M(t)u(k(t))]dt + b(k(t))dB(t)$
3. $dk(t) = [H(t)k(t) + M(t)u(k(t))]dt + b(k(t))dB(t)$

where $k$ is the capital, $M$ is the production, $u$ is control process, $H(t)$ be $n \times n$ positive matrices. For these stochastic economic models the optimal control for the first and second economic equation is found to be $u(t) = -\frac{M(t)Rx(T)G(t)}{G(t)}$, and the optimal control for the third equation is found to be $u(t) = -\frac{M(t)Rx(T)G(t)}{G(t)}$, and the optimal performance is

2. Definitions and Basic Concept

Definition (1), [3] A random experiment is a process that has random out comes.

Definition (2), [3] A sample space is the set of all possible outcomes of a random experiment and is denoted by $\Omega$.

Definition (3), [3] A $\sigma$-algebra $\mathcal{F}$ of subset of a sample space $\Omega$ (which is the set of all possible outcomes) satisfies the following
i. $\emptyset \in \mathcal{F}$.
ii. If $A \in \mathcal{F}$, then $A^c$ where $A^c$ is the complement of all set $A$. 

iii. For any sequence \( \{A_n\} \subseteq F \) then \( \bigcup_{n=1}^\infty A_n \in F \) and \( \bigcap_{n=1}^\infty A_n \in F \) the element of \( F \) and the pair \((\Omega, F)\) is called a measurable space.

**Definition (4), [3]**

The probability \( p \) is a set function that \( p: F \to [0, 1] \), and \( p \) is called a probability measure if the following conditions hold:

1. \( p(\emptyset) = 1 \).
2. \( p(A^c) = 1 - p(A) \).
3. \( p(\bigcup_{i=1}^\infty A_i) = \sum_{i=1}^\infty p(A_i) \), if \( A_i \cap A_j = \emptyset \), for \( i \neq j \).

**Definition (5), [3]**

The triplet \((\Omega, F, p)\) consisting of the sample space \( \Omega \), the \( \sigma \)-algebra \( F \) of subset of \( \Omega \) and a probability measure \( p \) defined on \( F \) is called a probability space.

**Definition (6), [3]**

A random variable \( x \), in the probability space \((\Omega, F, P)\) is a function \( x: \Omega \to \mathbb{R} \) such that the inverse \( x^{-1}(A) = \{w \in \Omega : x(w) \in A\} \subseteq F \) for all open subset \( A \) of \( \mathbb{R} \).

**Definition (7), [3]**

A stochastic process \( x: [0, T] \times \Omega \to \mathbb{R} \), in probability space \((\Omega, F, P)\) is a function such that \( x(t, .) \) is a random variable in \((\Omega, F, P)\) for all \( t \in (0, T) \) we will often write \( x(t) \equiv x(t, \omega) \).

**Definition (8), [3]**

A stochastic process \( x(t), t \geq 0 \), on a probability space \((\Omega, F, P)\) is adapted to the filtration \((F_t)_{t \geq 0}\) if for each \( t \geq 0 \), \( x(t) \) is \( F_t \) measurable.

**Definition (9), [3]**

A stochastic process \( x(t), t \geq 0 \), on a probability space \((\Omega, F, P)\) is adapted to the filtration \((F_t)_{t \geq 0}\) if for each \( t \geq 0 \), \( x(t) \) is \( F_t \) measurable.

\[
D_F = \sum_{i=1}^n \sum_{j=1}^n \frac{\partial f_j}{\partial x_i} (\int_0^1 r_{ij} dB^H) \eta_j \otimes r_{ij}(t) \tag{3}
\]

where \( \eta_j \in \mathcal{V}, r_{ij} \in L^2_{\mathbb{H}}([0, 1], L^2(0, \infty)) \).

**Definition (10), [8]**

The ordinary Brownian motion or (Wiener process) is Gaussian process \( B = \{ B(t), t \geq 0 \} \) with zero mean and covariance \( E(B(s)B(t)) = \min\{s, t\} \).

**Definition (11), [5]**

Let \( H \) be a constant belong to \((0, 1)\). A one dimensional fractional Brownian motion \( B^H = \{ B^H(t), t \geq 0 \} \) of Hurst index \( H \) a continuous and centered Gaussian process with zero mean and covariance function:

\[
E(B(s)B(t)) = \frac{1}{2}(t^{2H} + s^{2H} - |t - s|^{2H}) \text{ for } t, s \geq 0. \tag{12}, [9]
\]

**Definition (12), [9]**

Let \( S \) be a linear space of smooth cylindrical \( V \)-valued random variable on \((\Omega, F, P)\) such that if \( F \in S \) then it has the form

\[
F = \sum_{j=1}^n \int_0^1 r_{ij} dB^H \tag{1}
\]

where \( \eta_j \in \mathcal{V}, r_{ij} \in L^2_{\mathbb{H}}([0, 1], L^2(0, \infty)) \).

**Definition (13), [9]**

The derivative \( D: S \to L^2_{\mathbb{H}} \) is a linear operator which is given for \( F \in S \) in equation (1) by

\[
\frac{\partial f_j}{\partial x_i} (\int_0^1 r_{ij} dB^H) \eta_j \otimes r_{ij}(t) \tag{3}
\]

where \( \eta_j \in \mathcal{V}, r_{ij} \in L^2_{\mathbb{H}}([0, 1], L^2(0, \infty)) \).

Let \( f_1, f_2, \ldots, f_k \) are bounded Borel function on \( R^n \) and \( T \) be a stopping time and \( F_T \) is \( \sigma \)-algebra, then

\[
E_x[f(x_\alpha)] = E_x[E_x[f(x_{T_\alpha})]] = E_x[E_x[\theta_{\alpha} f(x_{T_\alpha}) | F_T]] = E_x[\theta_{T_\alpha} f(x_{T_\alpha})] = E_x[f(x_{T_\alpha})]. \tag{6}
\]

where \( T_\alpha = \inf\{ t > \alpha \} \)

\[
E_x[f(x_\alpha)] \leq E_x[f(x_{T_\alpha})] \tag{7}
\]

So \( f \) is supermeanvalued.
3. Fractional Stochastic Differential Equation

Let \( a(x(t)), b(x(t)) \) are continuous functional defined on the metric space \( K \), let the Fractional stochastic process \( x(t) \) satisfy the Fractional Stochastic Differential Equation

\[
dx(t) = a(x(t)) \, dt + b(x(t)) \, dB^H(t) \tag{8}
\]

and \( B^H(t) \) is Brownian motion.

Let \( H(t) \) be \( n \times n \) matrices, \( M(t) \) be \( n \times k \) matrices, \( b(t) \) be \( n \times m \) matrices and the control \( u(t) \) be \( k \times 1 \) vector and \( B(t) \) is Brownian motion let

\[
a(x(t)) = H(t) x(t) + M(t) u(t) \tag{9}
\]

and

\[
b(x(t)) = b(t) \tag{10}
\]

then from (8) and (9) the stochastic process \( x(t) \) in (7) satisfy the linear Fractional Stochastic Differential Equation

\[
dx(t) = H(t)x(t) + M(t)u(t) + b(t) dB^H(t) \tag{11}
\]

**Remark (2)**, "The ITO Fractional Taylor formula", [9]

Let \( x(t) \) be the stochastic process given as

\[
x(t) = x(0) + \int_0^t (H(t)x(t) + M(t)u(t)) \, dt + \int_0^t b(t) \, dB^H(t) \tag{12}
\]

Wherea \( a(x(t)), b(x(t)) \) are continuous functional defined on the metric space \( K \), the Hurst parameter \( H \in (\frac{1}{2}, 1) \) and \( V \) is separable Hilbert space. Let \( f: V \to V \) be a twice continuously differentiable function such that \( f': V \to S(V, V) \) and \( f'': V \to S(V, V) \) where \( f' \) and \( f'' \) are the first and second derivatives respectively for \( p, q \in [0, t] \) and \( V, \), then the process \( f(x(t)) \) satisfies the ITO Fractional Taylor formula defined by the ITO Formula

\[
f(x(t)) = f(x(0)) + \int_0^t \frac{df}{dx}(x(t)) a(t) \, dt + \int_0^t \frac{d^2 f}{dx^2}(x(t)) b(t) \, dB^H(t) + \int_0^t \int_0^t \left( \int_0^p \frac{d^2 f}{dx^2}(x(p)) \, dp \right) \, dq \, dt \tag{13}
\]

by taking the derivative of both saided one can get

\[
\frac{df}{dx}(x(t)) a(t) \, dt + \int_0^t \frac{d^2 f}{dx^2}(x(t)) b(t) \, dB^H(t) + \int_0^t \int_0^t \left( \int_0^p \frac{d^2 f}{dx^2}(x(p)) \, dp \right) \, dq \, dt \tag{14}
\]

by applying (7) on (13) to get

\[
\frac{df}{dx}(x(t)) [H(t)x(t) + M(t)u(t)] + \int_0^t \int_0^t \left( \int_0^p \frac{d^2 f}{dx^2}(x(p)) \, dp \right) b(q) \, dB^H(t) \, dq \, dt \tag{15}
\]

**Definition (15)** [5]

The generator \( A^u \) of an Fractional Stochastic differential equation (7) defined by

\[
A^uf = \frac{E[ df(x(t)) ]}{dt} \tag{16}
\]

**Remark (3)**

by substituting equation (15) in equation (16) eyelid that

\[
A^uf = \frac{df}{dx}(x(t)) [H(t)x(t) + M(t)u(t)] + \int_0^t \int_0^t \left( \int_0^p \frac{d^2 f}{dx^2}(x(p)) \, dp \right) b(q) \, dB^H(t) \, dq \, dt \tag{17}
\]

3.1. Fractional Martingale Problem

If (7) is an ITO Fractional Stochastic Differential Equation with generator \( A^u \) and \( f \in C^2(R) \) then the Fractional Martingale formula is
\[ f(x(t)) = f(x(0)) + \int_0^t A^u_x f \, dt + \frac{d^2 f(x(t))}{dx^2} b(t) \, dB^H(t) \, dt + \int_0^t A^u \frac{d f(x(p))}{dx} b(p) \, \varphi_H(p) \, dq \, dp \, dt \] (18)

3.2. Dynkin Formula for the Linear Quadratic Regulator Problem

Let \( h \in W^2(R) \), \( C(t) \) be the \( n \times n \) matrices and \( G(t) \) be the \( k \times k \) matrices. Note that from equation (11) and equation (17) we obtain the following Fractional Taylor formula for the function \( h(x(t)) \) where \( h(x(t)) \) defined as

\[ h(x(t)) = x^T(t)C(t)x(t) + G(t) \] (19)

\[ h(z(t)) = h(z(0)) + \int_0^t \left[ \frac{dh}{dx}(x(t)) \right] \left[ (H(t)x(t) + M(t)u(t)) + \frac{d^2 h(x(p))}{dx^2} b(q) b(p) \, \varphi_H(p-q) \, dq \, dp \right] dt \] (20)

Let \( T \) be a stopping time for the stochastic process \( x(t) \) defined in equation (12) such that \( E(\int_0^T A^u h(x(t)) \, dt) < \infty \), by taking the expectation of two sides, one can get the following Dynkin formula

\[ E(h(x(T))) = h(x(0)) + E\left[ \int_0^T A^u h(x(t)) \, dt \right] \] (21)

3.3. The Quadratic Regulator Optimal Problem

Assume that the cost function of the fractional linear quadratic regulator function is

\[ h(x, u) = E (x(T) R x(T) + \int_0^T (x^T(t) C(t)x(t) + u^T(t) G(t) u(t)) \, dt) \] (22)

where all of the coefficients \( C(t) \) be the \( n \times n \) matrices, \( G(t) \) be the \( k \times k \), the control \( u(t) \) be \( k \times 1 \) vector, we assume that \( C(t) \) and \( R \) are symmetric, non negative definite and \( G(t) \) is symmetric positive definite and \( T \) is the final time of the solution \( x(t) \) where \( x(t) \) defined in (3. 4) such that \( E|x(T)| < \infty \), the problem is to find the optimal control \( u^*(t) \) such that

\[ h(x, u^*(t)) = \min\{h(x, u)\} \]

4. Hamilton-Jacobi-Bellman Equation for Quadratic Regulator Problem

Consider the Markova Control \( u(t) = u(x(t)) \)

\[ A^u h = \frac{dh}{dx}(x(t)) \left[ (H(t)x(t) + M(t)u(t)) + \int_0^t \frac{d^2 h(x(p))}{dx^2} b(q) b(p) \, \varphi_H(p-q) \, dq \, dp \right] + A^u h^*(x) \] (23)

**Theorem (1) “HJB equation”**

Define \( h^*(x) = \min\{h(x, u)\} \) -Markov control

\[ u = u(t) \]

Suppose that \( h \in C^2(R) \) and the optimal control \( u^* \) exists Then

\[ \min\{x^T(t) C(t) x(t) + u^T(t) G(t) u(t) + A^u h^*(x) \} = 0 \] (25)

where \( G(t) \) be the \( k \times k \) metrics, the control \( u(t) \) be \( k \times 1 \) vector, and the generator \( A^u \)is given by equation (22) and

\[ h^*(x) = x^T(T) R x(T) \] (26)

The minim is a chivied when \( u^* \) is optimal. In other words

\[ x^T(t) C(t) x(t) + u^T(t) G(t) u(t) + A^u h^*(x) = 0 \] (27)

**Proof**

Now proceed to prove (7. 4), let \( \alpha = Tv \) be the first exit time of the solution \( x(t) \) by using (2. 5) and (2. 6)

\[ E_x [h(x(\alpha), u)] = E_x \left[ \int_0^{\alpha} (x^T(t) C(t) x(t) + u^T(t) G(t) u(t)) \, dt + x(T)^T R x(T) \right] \]
\[E_x [E_{x} \int_{0}^{T} (x^T(t) C(t) x(t) + u^T(t) G(t) u(t)) dt + x^T(t) R x(T) / F_x] =E_x \left[ \int_{0}^{T} (x^T(t) C(t) x(t) + u^T(t) G(t) u(t)) dt \right. \\
- \left. f^\alpha_0 [x^T(t) C(t) x(t) + u^T(t) G(t) u(t)] dt \right]\]

\[E_x [h(x, u)] = h(x, u) - E_x \left[ \int_{0}^{T} (x^T(t) C(t) x(t) + u^T(t) G(t) u(t)) dt \right]\]

Thus

\[h^*(x) \leq h(x, u) = E_x \left[ \int_{0}^{T} (x^T(t) C(t) x(t) + u^T(t) G(t) u(t)) dt \right] + E_x [h(x, u)] \]

by equation (21), we get

\[E_x [h(x, u)] = h(x) + E_x \int_{0}^{T} A^u h^*(x) dt \]

\[h^*(x) \leq h(x, u) = E_x \left[ \int_{0}^{T} (x^T(t) C(t) x(t) + u^T(t) G(t) u(t)) dt \right] + h(x) \]

\[+ E_x \int_{0}^{T} A^u h^*(x) dt \]

Or

\[0 \leq E_x \left[ \int_{0}^{T} (x^T(t) C(t) x(t) + u^T(t) G(t) u(t)) dt \right] + E_x \int_{0}^{T} A^u h^*(x) dt \]

At \( \alpha \to 0 \). Thus

\[0 \leq E_x [x^T(t) C(t) x(t) + u^T(t) G(t) u(t)] + A^u h^*(x) \]

by equation (6) we have

\[0 \leq x^T(t) C(t) x(t) + u^T(t) G(t) u(t) + A^u h^*(x) \]

*Theorem (2). (covers of the HJB equation)*

let \( h^*(x) \) be a bounded function in \( C(G)^2 \cap C(CL(G)) \), Suppose that for all \( u \in Y \) where \( Y \) is the set of controlothe inequality

\[x^T(t) C(t) x(t) + u^T(t) G(t) u(t) + A^u h^*(x) \geq 0 \]

then \( h^*(x) \leq h(x, u) \), for all \( u \in Y \), moreover

\[x^T(t) C(t) x(t) + u^T(t) G(t) u(t) + A^u h^*(x) = 0, \]

\( u^* \) is an optimal controle

*Proof*

Let \( u \) be a Markov control, and let \( u \) be a Markova control then

\[A^u h^*(x) \geq - [x^T(t) C(t) x(t) + u^T(t) G(t) u(t)] \]

by equation (21)

\[E_x [h^*(x))] = h(x) + E_x \int_{0}^{T} A^u h^*(x) dt \]

\[\geq h(x) - E_x \int_{0}^{T} x^T(t) C(t) x(t) + u^T(t) G(t) u(t) dt \]

Thus

\[h(x) \leq E_x [h^*(x)] + \int_{0}^{T} x^T(t) C(t) x(t) + u^T(t) G(t) u(t) dt = h(x, u) \]

\( u^* \) is an optimal controle.

5. Application 1 [Economics Model and It’s Optimization [Fractional Stochastic Differential Equation]]

In 1928 F. R Ramsy introduced an economics model describing the rate of change of capital \( K \) and labor \( L \) in a market by a system of ordinary differential equation with \( P \) and \( C \) being the production and consumption rates – respectively the model is given by

\[\frac{dK(t)}{dt} = p(t) - C(t), \quad \frac{dL(t)}{dt} = a(t) L(t) \quad (29)\]

Where \( a(t) \) is the rate of growth Labor.

The production, capital and labor are related by the Cobb–Douglas formula.
The production rate is subject to small random disturbances i.e. 

\[ p(t) = H(t) k(t) \]

where \( A, \alpha, \beta \) are some positive constants.

in certain the dependence of \( P \) on \( K \) and \( L \) is linear which will be our assumption throughout this section we shall also assume that the labor is constant, \( L(t) = L_0 \), which is true for certain markets or relatively short time intervals of several years.

Therefore the production rate and the capital are related by

\[ p(t) = H(t) k(t) + b(k(t))dB^H \]

Therefore

\[ \frac{dk(t)}{dt} = H(t)k(t) + b(k(t))dB^H - C(t) \]

Where \( M(t) = -C(t) \)

Which can be rewritten in the differential form as

\[ \frac{dk(t)}{dt} = [H(t)k(t) + M(t)]dt + b(k(t))dB^H \]

Where \( B^H \) is fractional Brownian motion \( b(k(t)) \) is real function, characteristic of the noise.

Assume that \( M(t) \) can be controlled

\[ \frac{dk(t)}{dt} = [H(t)k(t) + u(t)]dt + b(k(t))dB^H \quad (30) \]

Usually one wants to minimize the cost function let us choose the following cost function

\[ h(x, u) = E(\langle x^T(t) R x(t) + \int_0^T (x^T(t) C(t) x(t) + u^T(t) G(t) u(t)) dt \rangle) \]

The operator on \( h(x(t)) = \langle x^T(T) R x(T) \rangle \)

\[ A^h(x(t)) = [\frac{d}{dx} (\langle x^T(t) R x(t) \rangle)] (H(t)x(t) + M(t) u(t)) + \int_0^T \frac{d^2}{dx^2} (\langle x^T(t) R x(t) \rangle) b(q) b(p) \Phi_H(p-q) ds. \]

Since

\[ F'(x(t)) a(t) = [\frac{d}{dx} (\langle x^T(t) R x(t) \rangle)] (H(t)x(t) + M(t) u(t)) + \int_0^T F''(x(t)) d\alpha(t) dt + \Phi_H(p-q) \]

\[ \int_0^T F''(x(t)) b(q) b(p) \Phi_H(p-q) dt = 0 \]

\[ \int_0^T F''(x(t)) b(q) b(p) \Phi_H(p-q) dt = -\frac{1}{2} b(t) dB(t) + \frac{1}{2} b(t) dB(t) \]

by Theorem (1)

\[ \min \{x^T(t)c(t)x(t) + u^T(t)G(t) u(t) + 2 R x(T) H(t) x(t) + 2 R x(T) M(t) u(t) + \int_0^T 2R x(T) b(q) b(p) \Phi_H(p-q) dt = 0 \]

by taking the derivative of two sides, one can get,

\[ \frac{d}{du} [x^T(t) C(t) x(t) + u^T(t) G(t) u(t) + 2 R x(T) H(t) x(t) + 2 R x(T) M(t) u(t) + \int_0^T 2R x(T) b(q) b(p) \Phi_H(p-q) dt = 0 \]

\[ 2 G(t) u(t) + 2 R x(T) M(t) = 0 \]

Is optimal control for the linear-quadratic fractional Brownian motion differential equation and the optimal cost function is

\[ h(x, u) = E(\langle x^T(T) R x(T) + \int_0^T (x^T(t) C(t) x(t) + u^T(t) G(t) u(t)) dt \rangle) \]

6. Stratonovich Stochastic Differential Equation

Leta \( x(t) \), \( b(x(t)) \) are continuous function defined on the metric space \( K \), let the stochastic process \( x(t) \) satisfy the Stratonovich Stochastic Differential Equation

\[ dx(t) = \tilde{a}(x(t)) dt + b(x(t)) dB(t) \quad (31) \]

where

\[ \tilde{a}(x(t)) = a(x(t)) - \frac{1}{2} b(x(t)) \frac{dB(x(t))}{dx(t)} \quad (32) \]

and \( B(t) \) is Brownian motion.

Let \( H(t) \) be \( n \times n \) matrices, \( M(t) \) be \( n \times k \) matrices, \( b(t) \) be \( n \times m \) matrices and the control \( u(t) \) be \( k \times 1 \) vector, let

\[ a(x(t)) = H(t)x(t) + M(t) u(t) \]

\[ b(x(t)) = b(x(t)) dB(t) \]

then from (31) and (32) the stochastic process \( x(t) \) in (28) satisfy the linear Stratonovich Stochastic Differential Equation

\[ dx(t) = H(t) x(t) + M(t) u(t) - \frac{1}{2} b(t) dB(t) + b(t) dB(t) \quad (33) \]

\[ \tilde{a}(x(t)) = H(t)x(t) + M(t) u(t) - \frac{1}{2} b(t) dB(t) + b(t) dB(t) \quad (34) \]

\[ \text{And equation (30) become} \]

\[ b(t) dB(t) = b(t) dB(t) + \frac{1}{2} b(t) \frac{dB(t)}{dx(t)} \quad (35) \]

Remark (4), “The ITO Stratonovich Taylor Formula”

Let the stochastic process \( x(t) \) defined as
\[ x(t) = x(0) + \int_0^t a(x(t)) \, dt + \int_0^t b(x(t)) \, dB(t) \]  

where \( a(x(t)) \), \( b(x(t)) \text{d}B(t) \) are defined in equation (31) and equation (32) respectively, and \( a(x(t)), b(x(t)) \) are continuous functionals defined on the metric space \( K \), then \( x(t) \) satisfy the ITO Stratonovich Taylor Formula for \( f: R \rightarrow R \)

\[ f(x(t)) = f(x(0)) + \int_0^t \frac{df(x(t))}{dx} \, dt + \int_0^t \frac{df(x(t))}{dx} \, dB(t) \]

by applying (6.4) and (6.5) on (6.8) to get the ITO Formula

\[ f(x(t)) = f(x(0)) + \int_0^t \frac{df(x(t))}{dx} \, dt + \int_0^t \frac{df(x(t))}{dx} \, dB(t) \]

by taking the derivative of two sides, one can get,

\[ df(x(t)) = [\frac{d(H(t)x(t))}{dt} + \frac{d(M(t)u(t))}{dt}] \, dt + [\frac{d(b(t))}{dt} \, dB(t)] + \frac{1}{2} \, \frac{d(b(t))}{dt} \, dB(t) \]

Remark (5)
By definition (15) The generator \( A^u \) of an Stratonovich Stochastic differential equation is

\[ (A^u f)(x) = (H(t)x(t) + M(t)u(t)) \, \frac{df(x(t))}{dx} - \frac{1}{2} \, \frac{d(b(t))}{dt} \, \frac{df(x(t))}{dx} \, dB(t) + \frac{1}{2} \, \frac{d(b(t))}{dt} \, \frac{df(x(t))}{dx} \, dB(t) \]

6.1. The Martingale Problem
If (30) is an Stratonovich Stochastic Differential Equation with generator \( A^u \) and \( f \in C^2(\mathbb{R}) \) then

\[ f(x(t)) = f(x(0)) + \int_0^t A^u \, dt + \int_0^t b(t) \, \frac{df(x(t))}{dx} \, dB(t) \]

6.2. Dynkin Formula for Fractional Stochastic Linear Quadratic Regulator Problem with Stratonovich Formula
Let \( h(x(t)) = x^T(t) C(t) x(t) + G(t) \)

\[ h(x(t)) = h(x(0)) + \int_0^t [H(t)x(t) + M(t)u(t)] \, \frac{d(b(t))}{dt} \, dB(t) + \frac{1}{2} \, \frac{d(b(t))}{dt} \, dB(t) \]

Let \( T \) be a stopping time for the stochastic process \( x(t) \) such that

\[ E(\int_0^T A^u h(x(t)) \, dt) < \infty \]

by taking the expectation of two sides, one can get the following Dynkin formula

\[ E(h(x(T))) = h(x(0)) + E[\int_0^T [H(t)x(t) + M(t)u(t)] \, \frac{d(b(t))}{dt} \, dB(t) + \frac{1}{2} \, \frac{d(b(t))}{dt} \, dB(t) \]

6.3. The Fractional Stochastic Quadratic Regulator Optimal Problem
Assume that the cost linear quadratic regulator function is

\[ h(x, u) = E(x(T)^T R x(T) + \int_0^T (x^T(t) C(t) x(t) + u^T(t) G(t) u(t)) \, dt) \]

where all of the coefficients \( C(t) \) be the \( n \times n \) matrices, \( G(t) \) be the \( k \times k \) matrices, and \( R \) be the symmetric positive definite and \( T \) is the final time of the solution \( x(t) \) where \( x(t) \) defined in (25) such that \( E_x[T] < \infty \), the problem is to find the optimal control \( u^* \) such that

\[ h(x, u^*) = \text{min} \{ h(x, u) \} \]

6.4. Hamilton-Jacobi-Bellman Equation for Quadratic Regulator Problem
Let the optimal control \( u^* \) be Markov control, and the generator \( A^u \) is given in equation (42) and

\[ \text{Theorem (3)} \quad \text{"HJB equation"} \]

Define \( h^*(x) = \text{min} \{ h(x, u) : u = u(t) - \text{Markov control} \} \)

Suppose that \( h \in C^2(\mathbb{R}) \) and the optimal control \( u^\ast \) exists Then

\[ \min \{ x^T(t) C(t) x(t) + u^T(t) G(t) u(t) + A^u h^*(x) \} = 0 \]

where \( G(t) \) be the \( k \times k \) metrics, the control \( u(t) \) be \( k \times 1 \) vector, and the generator \( A^u \) is given in equation (42) and
\[ h^*(x) = x(T)^TRx(T) \]

The minim is aчивied when \( u^* \) is optimal. In other words
\[ x^T(t)C(t)x(t) + u^*^T(t)G(t)u^*(t) + A^u^*h^*(x) = 0 \]

**Proof**

Now proceed to prove (43), let \( \alpha = Tv \) be the first exit time of the solution \( x(t) \) by using (4) and (5)
\[
E_x[h(x(\alpha),u)] = E_x[E_x[\int_0^\alpha (x^T(t)C(t)x(t) + u^T(t)G(t)u(t))dt + x(T)^TRx(T)]
\]
\[
= E_x[E_x[\int_0^\alpha (x^T(t)C(t)x(t) + u^T(t)G(t)u(t)) + x(T)^TRx(T)]]
\]
\[
= E_x[\int_0^\alpha x^T(t)C(t)x(t) + u^T(t)G(t)u(t) - \int_0^\alpha u^T(t)G(t)u(t)]dt]
\]
\[
E_x[h(x,u)] = E_x[\int_0^\alpha (x^T(t)C(t)x(t) + u^T(t)G(t)u(t))dt + E_x[h(x,u)]
\]

by equation (37)
\[
E_x[h(x,u)] = h(x) + E_x[\int_0^\alpha u^T(t)G(t)u(t)dt] + h(x) + E_x[\int_0^\alpha A^u^*h^*(x)dt]
\]
\[
0 \leq E_x[\int_0^\alpha x^T(t)C(t)x(t) + u^T(t)G(t)u(t)dt = E_x[\int_0^\alpha A^u^*h^*(x)dt]
\]

At \( \alpha \to 0 \). Thus \( 0 \leq E_x[h(x,u)] \)

**Theorem (4), (conver of the HJB equation)**

let \( h^*(x) \) be a bounded function in \( C^2 \cap C(\mathbb{R}) \)

Suppose that for all \( u \in Y \) where \( Y \) is the set of control of the inequality
\[ x^T(t)C(t)x(t) + u^T(t)G(t)u(t) + A^u^*h^*(x) \geq 0 \]

then \( h^*(x) \leq h(x,u) \), for all \( u \in Y \), moreover
\[ x^T(t)C(t)x(t) + u^T(t)G(t)u(t) + A^u^*h^*(x) = 0, \text{ Then } u^* \text{ is an optimal controle} \]

**Proof**

Let \( u \) be a Markov control, and let \( u \) be a Markova control then
\[ A^u^*h^*(x) \geq -x^T(t)C(t)x(t) + u^T(t)G(t)u(t) \]

by equation (37)
\[
E_x[h(x,u)] = h(x) + E_x[\int_0^\alpha A^u^*h^*(x)dt]
\]
\[
\geq h(x) - E_x[\int_0^\alpha x^T(t)C(t)x(t) + u^T(t)G(t)u^*(t)dt]
\]

Thus\[ h(x) \leq E_x[h(x) + \int_0^\alpha x^T(t)C(t)x(t) + u^T(t)G(t)u^*(t)dt]
\]

**Application 2 [Economics Model with Brownian Strömovich Differential Equation]**

In 1928 F. R Ramsy introduced an economics model describing the rate of change of capital \( K \) and labor \( L \) in a market by a system of ordinary differential equation with \( P \) and \( C \) being the production and consumption rates — respectively the model is given by
\[
\frac{dK(t)}{dt} = p(t) - C(t), \quad \frac{dL(t)}{dt} = a(t)L(t)
\]

Where \( a(t) \) is the rate of growth Labor.

The production, capital and labor are related by the Cobb—Douglas formula.
\[
p(t) = Ak(t)\alpha L(t)\beta
\]

where \( A, \alpha, \beta \) are some positive constant. In certain the
dependence of $P$ on $K$ and $L$ is linear these mean $\alpha = \beta = 1$ which will be our assumption throughout this section we shall also assume that the labor is constant, $L (t) = L_0$; which is true for certain markets or relatively short time intervals of several years.

Therefore the production rate and the capital are related by

$$ p (t) = H (t) k (t) [1] $$

A nether important assumption we make is that the production rate is subject to small random disturbances i.e

$$ p(t) = H (t) k (t) + b (k (t)) \circ dB (t) $$

therefore

$$ \text{Which can be rewritten in the differential form as} $$

$$ \text{Where } M(t) = - C(t) $$

$$ \text{usually one wants to minimize the cost function (38) let } h^* (x) = x^T (T) R x (T), \text{ and let } h^* (x (T)) = D (A^u h^* ) $$

$$ \text{and then } (A^u h^*) = 0 $$

$$ \text{Then equation (43) become} $$

$$ x^T (t) C (t) x (t) + u^T (t) G (t) u (t) + H (t) x (t) 2 R x (t) + M (t) u (t) 2 R x (T) - b (k (t)) R x (T) \frac{db (k (t))}{dk (t)} = 0 $$

by taking the derivative of two sides, one can get,

$$ \frac{d}{dt} \left[ x^T (t) C (t) x (t) + u^T (t) G (t) u (t) + H (t) x (t) 2 R x (T) + M (t) u (t) 2 R x (T) - b (k (t)) R x (T) \frac{db (k (t))}{dk (t)} \right] = 0 $$

$$ 2u (t) G (t) + M (t) 2 R x (t) = 0 $$

$$ u (t) = - \frac{M (t) R x (T)}{G(t)} $$

is an optimal control for stratonovich stochastic linear quadratic differential equation and the optimal cost function is

$$ h (x, u) = E \left[ x (T) ^T R (x (T)) + \int_0^T \left( x^T (t) C (t) x (t) + \frac{M (t) R x (T)}{G(t)} \right) dt \right] $$

**8. Fractional Stratonovich Stochastic Differential Equation**

Let $a (x (t))$ and $b (x (t))$ are continuous functional defined on the metric space $K$, let the fractional stochastic process $x (t)$ satisfy the Fractional Stratonovich Stochastic Differential Equation

$$ dx (t) = \tilde{a} (x (t)) dt + b (x (t)) \circ dB^H (t) $$

where $\tilde{a} (x (t)) = a (x (t)) - \frac{1}{2} b (x (t)) \frac{db (x (t))}{dx (t)}$, and

$$ b (x (t)) \circ dB^H (t) = b (x (t)) dB^H (t) + \frac{1}{2} b (x (t)) \frac{db (x (t))}{dx (t)} $$

and $B^H (t)$ Fractional is Brownian motion.

Let $H (t)$ be $n \times n$ matrices, $M (t)$ be $n \times k$ matrices, $b (t)$ be $n \times m$ matrices and the control $u (t) \in k \times 1$ vector, let $a (x (t)) = H (t) x (t) + M (t) u (t)$ and $b (x (t)) = b (t)$, then (34) become

$$ \tilde{a} (x (t)) = H (t) x (t) + M (t) u (t) - \frac{1}{2} b (t) \frac{db (x (t))}{dx (t)} $$

and equation (35) become

$$ b (t) \circ dB^H (t) = b (x (t)) dB^H (t) + \frac{1}{2} b (x (t)) \frac{db (x (t))}{dx (t)} $$

then from equation (60) and equation (61) the fractional stochastic process $x (t)$ in equation (57) satisfy the Fractional Linear Stratonovich Stochastic Differential Equation

$$ dx (t) = H (t) x (t) + M (t) u (t) - \frac{1}{2} b (t) \frac{db (x (t))}{dx (t)} $$

**Remark (6), 'The ITO Fractional Stratonovich Taylor Formula'**

Let the stochastic process $x (t)$ defined as

$$ x (t) = x (0) + \int_0^t \tilde{a} (x (t)) dt + \int_0^t b (t) \circ dB^H (t) $$

where $\tilde{a} (x (t))$, $b (t) \circ dB^H (t)$ are defined in equation (58) and equation (59) respectively, and $a (x (t)), b (x (t))$ are continuous functional defined on the metric space $K$, then $x (t)$ satisfy the ITO Fractional Stratonovich Taylor Formula for $f: R \rightarrow R$

$$ f (x (t)) = f (x (0)) + \int_0^t \frac{df (x (t))}{dx} \tilde{a} (x (t)) dt + \int_0^t \frac{df (x (t))}{dx} b (x (t)) \circ dB^H (t) $$

$$ \Phi_H (p, q) dqdp + \int_0^t \int_0^p \frac{df (x (t))}{dx} b (x (t)) dq b (p) \Phi_H (p, q) dqdp $$

by applying equation (58) and equation (59) on equation (64)
to get the ITO Formula
\[ f(x(t)) = f(x(0)) + \int_0^t \frac{df(x(t))}{dx}(H(t) x(t) + M(t) u(t)) dt \]
\[ - \frac{df(x(t))}{dx} \frac{1}{2} b(t) \]
\[ \frac{db(t)}{ds} ] dt+ \int_0^t \int_0^t \frac{df(x(t))}{dx} \frac{1}{2} b(t) \]
\[ \frac{dp^2}{dx^2} [ D_q (b(t)) dB^H (t) b(p) \Omega_H (p-q) \]
\[ \frac{1}{2} B_q (b(t)) (D_q^2 b(t)) ] dqdt \]

By taking the derivative of two sides, one can get,
\[ \frac{df(x(t))}{dx} = \frac{df(x(t))}{dx} \frac{1}{2} b(t) \]
\[ \frac{db(t)}{ds} ] dt+ \int_0^t \int_0^t \frac{df(x(t))}{dx} \frac{1}{2} b(t) \]
\[ \frac{dp^2}{dx^2} [ D_q (b(t)) dB^H (t) b(p) \Omega_H (p-q) \]
\[ \frac{1}{2} B_q (b(t)) (D_q^2 b(t)) ] dqdt \]

Remark (7)
by using substitution equation (66) in equation (16) one get that
\[ (A^h) = 2C(t) x(t) H(t) x(t) + 2C(t) x(t) M(t) u(t) + \int_0^T 2C(t) b(q) b(p) \Omega_H (p-q) dq \]

8.1. The Fractional Stratonovich Martingale Problem
If \( f(x(t)) = f(x(0)) + \int_0^t A^h b(t) dB^H (t) + \frac{1}{2} b(t) \)

8.2. Dynkin Formula for the Fractional Linear Stratonovich Quadratic Regulator Problem
Let \( h(x(t)) = h(x(0)) + \int_0^T 2C(t) x(t) H(t) x(t) + 2C(t) x(t) M(t) u(t) + \int_0^T 2C(t) b(q) b(p) \Omega_H (p-q) dq \)

8.3. The Fractional Stochastic Quadratic Regulator Optimal Problem with Stratonovich
We assume that the cost linear quadratic regulator function is
\[ h(x, u) = E(x(T)) R x(T) + \int_0^T (x(T) C(t) x(t) + u(T) C(t) u(t)) dt \]

where all of the coefficients \( C(t) \) be the \( n \times n \) matrices, \( G(t) \) be the \( k \times k \), the control \( u(t) \) be \( k \times 1 \) vector, we assume that \( C(t) \) and \( R(t) \) are symmetric, non negative definite and \( G(t) \) is symmetric positive definite and \( T \) is the final time of the solution \( x(t) \) where \( x(t) \) defined in(12). Then such that \( E_q[T] \)
the problem is to find the optimal control \( u^* (t) \) such that

\[
h (x, u^* (t)) = \min \{ h (x, u) \}
\]

(76)

9. Hamilton-Jacobi-Bellman Equation for Fractional Stochastic Quadratic Regulator Problem

Let the optimal control \( u^* (t) \) be \( \in \mathcal{Y} \) where \( \mathcal{Y} \) is the set of control then the generator in equation (16) become

\[
(A^u h) = 2C (t) x (t) \mathbf{H} (t) x (t) + 2C (t) x (t) M (t) u^* (t)
\]

\[
+ \int_0^T 2C (t) b (q) b (p) \varphi_H (p-q) \, dq
\]

(77)

Theorem (5) “HJB equation”

Define \( h^* (x) = \min \{ h (x, u); u = u (t) - \text{Markov control} \} \) (78)

Suppose thath be \( \in C^2 (\mathbb{R}) \) and the optimal control \( u^* \) exists

Then

\[
\min \{ x^T (t) C (t) x (t) + u^T (t) G (t) u (t) + A^u h^* (x) \} = 0 \quad (79)
\]

where \( G(t) \) be the k×k metrics, the control \( u (t) \) be k×1 vector, and the generator \( A^u \) is given by equation (77) and

\[
h^* (x) = x (T) \mathbf{T} \mathbf{R} x (T)
\]

(80)

The minim is a chieved whenu^* is optimal. In other words

\[
x^T (t) C (t) x (t) + u^T (t) G (t) u (t) + A^u h^* (x) = 0 \quad (81)
\]

Proof

Now proceed to prove equation (81), let \( \alpha = T \nu \) be the first exit time of the solution \( x (t) \) by using (4) and equation (5)

\[
E_x [ h (x, u), \alpha ] = E_x [ E_x [ \int_0^\alpha (x^T (t) C (t) x (t) + u^T (t) G (t) u (t) ) \, dt + x^T (t) R x (T) ]]
\]

\[
= E_x [ \int_0^\alpha (x^T (t) C (t) x (t) + u^T (t) G (t) u (t) ) \, dt + x^T (t) R x (T) ] / F_\alpha ]
\]

\[
= E_x [ \int_0^\alpha (x^T (t) C (t) x (t) + u^T (t) G (t) u (t) ) \, dt
\]

\[
- \int_0^\alpha x^T (t) C (t) x (t) + u^T (t) G (t) u (t) ) \, dt]
\]

\[
= E_x [ h (x, u)] = h (x, u) - E_x [ \int_0^\alpha (x^T (t) C (t) x (t) + u^T (t) G (t) u (t) ) \, dt]
\]

Thus

\[
h (x, u) = E_x [ \int_0^\alpha x^T (t) C (t) x (t) + u^T (t) G (t) u (t) ) \, dt] + E_x [ h (x, u)]
\]

(82)

\[
h^* (x) \leq h (x, u) = E_x [ \int_0^\alpha x^T (t) C (t) x (t) + u^T (t) G (t) u (t) ) \, dt] + E_x [ h (x, u)]
\]

By equation (74)

\[
E_x [ h (x, u)] = h (x) + E_x [ \int_0^\alpha A^u h^* (x) \, dt]
\]

\[
h^* (x) \leq h (x, u) = E_x [ \int_0^\alpha A^u h^* (x) \, dt]
\]

10. Application 3 [Economics Model with Fractional Stratonovich Differential Equation]

In 1928 F. R. Ramsy introduced an economics model describing the rate of change of capital \( K \) and labor \( L \) in a market by a system of ordinary differential equation with \( P \) and \( C \) being the production and consumption rates respectively the model is given by

\[
\frac{dk}{dt} = p (t) - C (t), \quad \frac{dl}{dt} = a (t) L (t)
\]

(83)

Where \( a(t) \) is the rate of growth Labor.

The production, capital and labor are related by the Cobb-Douglas formula.

\[
p (t) = A k (t)^a L (t)^b
\]
where $A, \alpha, \beta$ are some positive constant.

In certain the dependence of $P$ on $K$ and $L$ is linear these mean $\alpha = \beta = 1$ which will be our assumption throughout this section we shall also assume that the labor is constant, $L(t) = L_0$; which is true for certain markets or relatively short time intervals of several years.

Therefore the production rate and the capital are related by

$$p(t) = H(t) k(t), \quad [1]$$

A neither important assumption we make is that the production rate is subject to small random disturbances i.e.,

$$p(t) = H(t) k(t) + b(k(t)) \circ dB(t).$$

Therefore

$$M(t) = -C(t)$$

Which can be rewritten in the differential form as:

$$\frac{dk(t)}{dt} = [H(t) k(t) + M(t)]dt + b(k(t)) \circ dB(t) \quad (84)$$

Where $B^H(t)$ is Fractional Brownian motion $b(k(t))$ is real function, characteristic of the noise, Assume that $M(t)$ can be controlled the equation $(84)$ become

$$\frac{dk(t)}{dt} = [H(t) k(t) + M(t)]u(k(t))dt + b(k(t)) \circ dB^H(t) \quad (85)$$

usually one wants to minimize the cost function $(75)$ let $g(x(T)) = x^T(T) R x(T)$, and let $h^*(x) \in D(A^h)$ and from definition $(15)$ then $(16)$ become

$$(A u h^*) x = 2Rx(T) H(t) x(t) + 2Rx(T) M(t) u(t) + \int_0^T 2Rb(q) b(p) \Phi_H(p - q) dq \quad (86)$$

Then $(81)$ become

$$h^*(x) + (A u h^*) = 0 \quad (87)$$

by taking the derivative of two sides, one can get,

$$\frac{d}{dt}[x^T(t) C(t) x(t) + u^T(t) G(t) u(t) + 2Rx(T) H(t) x(t) + 2Rx(T) M(t) u(t) + \int_0^T 2Rb(q) b(p) \Phi_H(p - q) dq] = 0$$

$$2G(t) u(t) + 2Rx(T) M(t) = 0$$

$$u(t) = -\frac{Rx(T) M(t)}{G(t)}$$

Is optimal control for the linear-quadratic fractional Brownian motion differential equation and the optimal cost function is

$$h(x, u) = E [x^T(T) R x(T) + \int_0^T (x^T(t) C(t) x(t) + (Rx(T) M(t))^2) dt]$$

References
