Abay Sefene, Dereje Birhanu, Worku Awoke, Tesfaye Taye. Determinants of Exclusive Breastfeeding Practice among Mothers of Children Age Less Than 6 Month in Bahir Dar City Administration, Northwest Ethiopia; A Community Based Cross-Sectional Survey. *Science Journal of Clinical Medicine*. Vol. 2, No. 6, 2013, pp. 153-159. doi: 10.11648/j.sjcm.20130206.12

Abstract: Background- Exclusive breastfeeding is the optimal feeding practice to achieve infants' growth and development. Most mothers breastfeed their children but malnutrition is still prevalent in Ethiopia. Factors affecting exclusive breastfeeding practice are less known in the study area. Therefore the study aimed to assess its determinants among mother of children age less than 6 months in Bahir Dar city administration, Ethiopia. Method: Community based cross sectional survey was conducted from Jan to Feb 2013. In Bahir Dar city administration there were a total 20 (12 Urban & 8 Rural) Kebles, of which 6 (4 Urban & 2 Rural) were selected randomly using lottery method. The registration of mothers who had a child age less than 6 months by the local HEW was used as a sampling frame. Data was collected using interviewer administered questionnaire and was entered and analyzed using SPSS version 16. Logistic regression was used to identify determinants. P value <0.05 was considered statistically significant. Results: A total of 159 mothers were interviewed (93.5% response rate). Respondent's mean age was 27.2±4.6 years, 2/3rd of respondents were housewives by occupation, and more than 90% of participants were urban residents and were married. Prevalence of exclusive breastfeeding was 49.1%. Mother education level (AOR=2.99), child sex (AOR=2.22), Parity (AOR=2.46), family size (AOR=2.92), and time of postnatal care (AOR=3.44) were independent predictors of exclusive breastfeeding practice in the study area. Conclusion & recommendation: Practice of exclusive breastfeeding was below the WHO recommendation and the target of the fifth Ethiopian Health Sector Development program. Mother education, child sex, parity, family size, and time of postnatal care were the independent predictors of exclusive breast feeding practice. The city administration should work on promoting exclusive breastfeeding practice giving special emphasis to educated mothers. The government should also consider revising the legislation of the two month postpartum maternity leave.

Keywords: Exclusive Breastfeeding, Under Six Month, Bahir Dar, Ethiopia

1. Introduction

Malnutrition has been responsible directly or indirectly for 60% of the 10.9 million annual deaths among children under five years of age. Infant and young child feeding practices affect the nutritional status of children under 2 years of age where about 40% of these deaths are associated with inappropriate feeding practices [1, 2].

According to the WHO recommendation, infants should be exclusively breastfed for the first six months and up to two years or beyond. Despite appropriate feeding practice is the most cost effective intervention to reduce child morbidity and mortality, only 38% of children less than 6 months of age are exclusively breastfed in the developing countries [3, 4].

Even though breastfeeding is a universally accepted and praised behavior in the Ethiopian culture in general and in

Amhara region in particular, only half (52%) of mothers practiced exclusive breastfeeding. Malnutrition in Ethiopia is the underlying cause for 57% of child deaths and the prevalence of stunting (43%) and wasting (12%) is much higher among Ethiopian under 3 years children [5, 6].

Despite studies were conducted in different parts of the country to assess the magnitude and determinants of exclusive breast feeding, the determinant factors for the practice of EBF were not known in the study area, hence the objective of the study was to identify the determinants among mothers of children age less than 6 months in Bahir Dar city administration, Northwest Ethiopia.

2. Methods

2.1. Study Design and Period

The study was a community based cross sectional survey and was conducted from Jan 2013 to Feb 2013.

2.2. Study Area and Setting

The study was conducted in Bahir Dar city administration of Amhara Region, located 564 km Northwest of Addis Ababa (capital city of Ethiopia). Bahir Dar city administration has a total of 20 Kebeles (12 urban and 8 rural). The total population of the administration in the year of 2011/2012 was 276, 450, of which 231,376 were Urban residents. The proportion of female residents was 141,627. A total of 37,321 under five children were living in the city administration, of which, 12,717 were less than 6 months of age. In the city administration, there were 1 referral hospital, 11 health centers and 10 health posts owned by government, and 2 general hospitals, 44 clinics owned by private organizations [7].

2.3. Population

Source populations: All mothers who had a child age less than 6 months and living in the city administration in the previous 6 months prior to the survey.

Study Populations: Mothers who had a child age less than 6 month in the randomly selected Kebele.

Study Unit: Mother who has a child age less than 6 months

Inclusion/exclusion criteria:

Mothers who had a child age less than 6 month and living in the study area for more than 6 months were included. Those who were not biological care giver or mothers who were unable to communicate due to serious illness at the time of data collection were excluded.

2.4. Sample Size Determination and Sampling Procedure

Sample Size Determination

The sample size was calculated using single population proportion formula by considering the following assumptions: a 95% confidence level, 5% margin of error, 12% proportion of exclusive breastfeeding practice [8]

$$n = \frac{(Z\alpha/2)^2 p (1-p)}{d^2} = \frac{(1.96)^2(0.12) (0.88)}{(0.05)^2}$$

therefore the sample size was 162, Where n- required sample size, Z- critical value for normal distribution at 95% confidence level (1.96), P- proportion of exclusive breastfeeding practice (12%), d= 0.05 (5% margin of error); and adding 5% non-response rate (8), total sample size required was 170.

2.4.1. Sampling Procedures

In Bahir Dar city administration, there were 20 Kebeles of which 12 were Urban and 8 Rural. From these 20 Kebeles, 6 (4 Urban and 2 Rural) kebeles were selected by simple random sampling using lottery method. On average the number of households in each Kebele and the number of people in each household was 1000 and 5 respectively making the total population at each Kebele about 5000. The number of study participants was allocated proportionally to each Kebele based on number of households in each kebele. The registration of mothers who had a child age less than 6 months by the local HEW was used as a sampling frame. Since six kebeles were selected to get 170 children age less than 6 month, about 28-29 children were selected at each Kebele and to get such children, four to six Gotes/Villages who had high dense households were identified jointly with HEW and mothers who had a child age less than 6 months were included in the study. We walk along the Gotes/Villages until the required sample was completed.

If more than one mother who had a child age less than 6 months was found in the same house, then the mother with the youngest child were selected. Lottery method was used if mothers had a child of the same age. If the eligible mother was absent from the house at the time of data collection, then revisit was done and if they were absent at second visit they were considered as non respondent.

2.4.2. Variables of the Study

The dependent variable was practice of exclusive breastfeeding and the independent variables were Sociodemographic/economic variables such as age of mother, marital status, residence, occupation, maternal education, ethnicity, religion, monthly income, husband education; and Health service related factors such as ANC attendance, staff advice on child feeding during ANC, PNC service use,...

2.4.3. Definitions of terms

Exclusive breastfeeding Practiced: A mother who feed only breast milk, and no other liquids or solids with the exception of oral rehydration solution, supplements or medicines to the child age less than 6 month since birth.

2.4.4. Data Collection Tools and Procedures

Semi structured interviewer administered questionnaire was developed to collect necessary information and it was adapted from the Ethiopian Health and Demographic Survey, and from the WHO infants and young child feeding guide line [6, 9]. The questionnaire was first developed in English and was translated in to the local language Amharic. Four

data collectors and one supervisor were recruited and trained for two days. Age of the child was calculated from the date of birth to the date of the survey. For those with written evidence, date of birth was obtained from child health cards and if they don't have written documents, age was established relying on the date given by the mother.

2.4.5. Data Quality Control Issues

Questionnaire was prepared in English and was translated in to the local language Amharic. Pre-testing of the questionnaire was made in non selected kebele and correction was made accordingly. Training was given to the data collectors and supervisor. Close supervision of the data collection was carried by the supervisor and investigators.

2.4.6. Ethical Considerations

The study was conducted after getting ethical clearance from Bahir Dar University, College of Medicine and Health Sciences ethical review board. Supportive letter was obtained from Amhara Regional Health Bureau and was given to Bahir Dar city administration health office and to the respective Kebeles. Informed consent was obtained from each study participant after the objective of the study was explained. Respondents were also told the right not to respond to the questions they don't want to respond or to terminate the interview at any time.

2.5. Data Management and Analysis

The questionnaire was checked manually for completeness and consistencies, and was then coded, entered, and analyzed using SPSS window version 16. Descriptive statistics was computed to determine prevalence of exclusive breastfeeding practice. To identify factors associated with exclusive breastfeeding practice, binary logistic regression analysis was carried at two levels, first bivariate logistic regression was performed to each independent variable with the outcome variable and variables with a p value < 0.2 were included in the final model (multivariate analysis). Strength of association was measured using odds ratio, and 95% confidence intervals. Statistical significance was declared at P value <0.05. The findings were presented in text and tables

3. Result

A total of 159 mothers of children age less than 6 month were interviewed making the response rate 93.5%. The mean age of the respondents was 27.2 ±4.6 years. More than two third (73.2%) of mothers were in the age range of 20-29 years. Of the total participants, 118 (74.2%) were Orthodox Christian religion followers, and 90% were urban residents. Almost all (97.5%) were Amhara ethnic groups, 39 (24.5%) of mothers were not able to read and write, and more than 2/3rd were housewives. Of the total participants, 46% earns an average family monthly income of less than 1000.00 ETB (53.00 US Dollar). Latrine and pipe water were available in 92.5%, and 86% of participants respectively [Table 1].

Maternal and Child Health Service and other Related Characteristics

Study subjects were asked whether they were attended ANC or not during their current pregnancy and 150 (94.3%) mothers reported that they received ANC service to the current child and more than 80% of respondents reported that they were told how long they should breastfeed the child. Nearly two third of mothers reported that they breastfeed their children 8 or more times in the previous 24 hours. Regarding to the sex of the child, fifty two percent were males. Practice of exclusive breastfeeding was reported in 49.1% of mothers. Among mothers who didn't exclusively breastfeed their children, the main reason reported was the perception that breast milk alone was insufficient (Table 2).

Determinants of EBF Practice

Exclusive breastfeeding was practiced in half of the study participants. With regard to the determinants of exclusive breastfeeding practice, each variable were assessed independently whether they were predictors of the practice of EBF or not. Predictor variables identified in the bivariate analysis were residence (COR =3.50, 95% CL (1.08-11.37)), maternal education level (COR=2.45, 95% CL (1.30-4.64)), and number of PNC visits (COR=2.50 (1.02-6.15)). Variables such as husband education, number of ANC visit, & family size were marginally significant but other variables included in the model were not significantly associated to the practice of EBF. Variables were included in the final multivariate logistic regression model to see their predictive effect on the practice of exclusive breastfeeding. Maternal education level and time of PNC attendance remained determinants of EBF practice in the multivariate model but residence which was significantly associated to the practice of EBF and Husband education and Number of ANC visits which were marginally associated in the bivariate model had lost their significance in the final model. At the same time child sex, parity, and family size which were not significantly associated to exclusive breastfeeding practice in the bivariate model, were significantly associated to the outcome variable in the final model. With regard to their predictive effect, mothers who were unable to read and write or completed primary school were 3 times more likely to exclusively breastfeed their child than those mothers who completed secondary school or more; AOR= 2.99, 95% CL (1.47- 6.07). Mothers who lived in a family member of five or more were about three times more likely to EBF their children than those who live in a family member of four or less; AOR= 2.92, 95% CL (1.11-7.72). With regard to the sex of the child, those mothers whose child was male were 2 times more likely to practice exclusive breastfeeding than those mothers whose child were female; AOR= 2.22, 95% CL (1.04- 4.73). Primipara mothers were more than 2 times to practice EBF than those mothers who were Multipara; AOR=2.46, 95% CL (1.12-5.40) and those mothers who attend postnatal care three times or more were 3 times more likely to practice exclusive breastfeeding than those who attend twice or less; AOR=3.44, 95% CL (1.30- 9.08) (Table 3).

4. Discussion

Breastfeeding is unequalled way of providing ideal food for the healthy growth and development of infants. As a global public health recommendation, infants should be EBF for the first 6 months because breast milk is uncontaminated and contains all the nutrients and antibodies that are very important to prevent disease [2].

4.1. Prevalence of EBF

In this study 49.1% of mothers reported that they were exclusively breastfeed their current child. The finding of the study was comparable to the 2011 Ethiopian DHS report (52%), the 2005 Ethiopian DHS report (49%), a study done in Harar Ethiopia (51.9%), Tanzanian 2010 national DHS report (49.9%), and a study done in the district of peninsular Malaysia (43.1%) [6, 10-13]. But the finding was lower than studies done in the Sri Lanka national DHS report (60.6%), Dinajpur district of Bangladesh (61.3%), in Legon district of Ghana (66%), in Dodoma municipality of Tanzania, in the rural district of Hoima of western Uganda (57%), and in Goba district of Ethiopia (73.5%) [14-19]

4.2. Determinants of EBF

This study was aimed to identify determinants of exclusive breastfeeding practice among mothers of children age less than 6 months in Bahir Dar city administration. Education is an important factor influencing individual's attitude and opportunities in life. Although educational attainment in Ethiopia is low among both men and women, women are much more disadvantaged than men. In this study about 50% of mothers were unable to read and write or in primary school. The finding was comparable to the Ethiopian national education prevalence (51%) but it was much better as compared to the prevalence report of Amhara region where 63.6% of adults were unable to read and write [6].

In the multivariate logistic regression model, maternal education was the independent determinant factor to the practice of EBF where mothers who were unable to read and write or in primary school were 3 times more likely to practice EBF than those who completed secondary school or higher. This might be explained by the fact that women who

were better educated could have a better opportunity for employment that could lead them to be out of house the whole day. In Ethiopia the maternity leave given during the postpartum period is only 2 month therefore this could also affect educated people not to exclusively breastfeed for the first 6 month. At the same time, women may be influenced by media advertising on milk substitutes which will further compromise the practice of EBF. The finding was in agreement to studies done in Saudi Arabia, Ethiopia, Sweden, and Vietnam, [8, 12, 20-21,], but the finding is not consistent with other studies such as in Colombo district of Sri Lanka, Canada national survey report, in the Thane district of India, and a study done in Singapore [22-25].

Feeding practices affect the child's nutritional status, which in turn risk the child to death. In this study mothers who had male children were two times more likely to exclusively breastfeed than those mothers who had female child. This might be due to cultural bias on the sex of the individual where in Ethiopian context more priority or respect is usually given to males than females. The finding was in agreement to studies done in Uganda, Egypt, and India [18, 24, 26-27]. But not in agreement to studies done in Singapore, and Nigeria [25, 28].

A large proportion of maternal and neonatal deaths occur during the first 48 hours after delivery, and these two days following delivery are critical for monitoring complications arising from the delivery and also to provide the mother with important information on how to care for herself and to her child. In this study 93.7% of mothers reported that they attend postnatal service and the proportion of mothers who attend postnatal care at 6 weeks, at 6 and at 10 weeks, and at 6, 10, and 14 weeks or more were 61%, 22.6% and 16.4% respectively. Mothers who attend PNC at 6, 10, and 14 weeks or more were 3 times more likely to practice exclusive breastfeeding than those who attend at 6 weeks only or at 6 and at 10 weeks only. This might be due to the fact that mothers who attend PNC frequently could be more counseled by health care workers to breastfeed their children exclusively. The finding is supported by the 2011 Ethiopian DHS report where the great majority (92%) of women didn't receive postnatal checkup and only 52% did EBF, and also a study done in Sri Lanka indicated that those mothers who didn't attend PNC were less likely to exclusively breastfeed their children than those who attend postnatal service [6, 14]

The number of pregnancy could affect the child feeding practice. In this study mothers who were primipara were two times more likely to exclusively breastfeed than Multipara mothers. This could be because of the fact that primipara mothers might be young people who could have better access to media and be more knowledgeable on advantage of exclusive breast feeding. The finding was in agreement to a study done in peninsular Malaysia [13] but was not consistent to studies done in Saudi Arabia, Canada, West India, and in the Thane district of India where multiparous mother were more likely to exclusively breastfeed than primipara mothers [8, 23, 24, 27].

Regarding to family size those mothers who had more families (four or more) were three times more likely to exclusively breastfeed than those who lived in a family size of three or less. This might be because those who had more family member could have better educated people that can convince or educate the mother to feed the baby exclusively.

Limitation of the Study

Since mothers were asked their 24 hour exclusive breastfeeding practice, some infants who were given other liquids regularly may not have received such fluids/foods in the last 24hrs before the survey which might overestimate the proportion of exclusive breastfeeding practice. Psychosocial variable which could address cultural/traditional practices were not included in the survey questionnaire.

5. Conclusion and Recommendation

Prevalence of EBF was much lower than the WHO recommendation, and Ethiopian national HSDP target. Mother education, child sex, parity, family size and time of PNC visit were the predictors for exclusive breastfeeding practice. Despite the majorities were urban residents, sex bias is still the major problem.

The administration should work on promoting behavior change communication on exclusive breastfeeding practice giving special emphasis to educated mothers. The government should also consider revising the legislation of the two month postpartum maternity leave. The administration should also address the problem of sex bias.
