Abstract: The effect of inoculation with the arbuscular mycorrhizal (AM) fungi on the resistance of mercury (Hg) in lonkida (*Nauclea orientalis*) seedlings were investigated using an artificially contaminated river sand media at the concentration of 0, 375 and 750 μM Hg at screen house. Mercury accumulation was lower in mycorrhizal roots than in non-mycorrhizal roots when Hg was added at the rates of 750 μM . However, Hg accumulation and its translocation to the leaves were very low, either in mycorrhizal or non-mycorrhizal seedlings. The amount of Hg retained in roots was higher than in leaves, irrespective of applying different Hg concentration. *N. orientalis* seedlings have a high tolerance to Hg (> 70%). Under these experimental conditions, *N. orientalis* shows a high resistance and capacity to retain Hg in roots. Mycorrhizal symbiosis showed a significant effect of the resistance to Hg of *N. orientalis* plants grown in Hg-polluted and Hg-unpolluted media. Furthermore, the beneficial effects of the AM fungi observed in this study aroused an interest in considering the role of AM fungi in plant-based strategies of remediation of highly Hg-polluted soils.

Keywords: *Nauclea Orientalis*, Mercury, Resistance, Arbuscular Mycorrhizal Fungi, Remediation

1. Introduction

Mercury is ranked third on The Agency for Toxic Substances and Disease Registry (ATSDR) 2011 Substance Priority List - a listing algorithm prioritizes substances based on frequency of occurrence at National Priorities List (NPL) sites - toxicity and potential for human exposure to the substances found at NPL sites [1]. Anthropogenic activities and the agricultural soils because of the annual import of toxic Hg [2]. Hg^{2+} causes toxicity symptoms in higher plants through adverse effects on biochemical and physiological process [2], reduces chlorophyll levels in leaves [3] and disturbs photosynthetic activity [4]. Change in uptake and translocation of mineral nutrients have been reported in the presence of Hg [5]. In addition, Hg triggers oxidative stress by inducing production of H_2O_2 , lipid peroxide, and reactive

oxygen species (ROS) in many plants, such as tomato, cucumber and alfalfa [6,7].

The use of plants and soil microbes for remediation of Hg-polluted is an emerging area of interest because it provides an ecologically sound and safe method. It has been proposed that plants can be used to remediate soils polluted with such element, either by stabilization, extraction, and volatilization [8-10]. Plants species selection is a key aspect for the success of remediation soils polluted and long-term reclamation of degraded lands. Hg accumulation in several plants has been studied, such as white clover [11], alfalfa [12], lentil, chickpea [13] and common vetch [14]. However, very few studies have been conducted on the Hg accumulation in tropical trees, such as *Nauclea orientalis*. *N. orientalis* is a pioneer species, a hardy species with dry land reclamation potential, and gives

some services to the environment, such as to controls soil loss on riparian areas (erosion control), and soil improver because leaf litter on decay replenishes soil fertility [15]. If this tree species is proposed for phytoremediation on Hg-polluted soil, plant Hg uptake and resistance response should be evaluated under controlled conditions, prior to field establishment a screen to identify suitable candidate species.

An alternative solution is to combine the advantages of microbe plant symbiosis in the plant rhizosphere into an effective clean-up technology. Arbuscular mycorrhizal (AM) fungi are ubiquitous soil, forming symbiotic associations with roots of the majority of plant species [16]. It has been addressed that mycorrhizal inoculation can affect the accumulation of metals such as Cu, Cd, Zn, and As by plants and enhance the tolerance of host plants to contamination of these metals in soil [17-19]. However, the behavior of Hg in mycorrhizal plants is still lack and the potential of AM fungi has not yet been fully explored with respect to its Hg phytoremediation potentials. The first report about the effects of mycorrhizal inoculation on Hg behavior in soil-plant system is done [20] and it has been shown that Hg uptake was lower by mycorrhizal roots of maize than by non-mycorrhizal roots.

The interaction between AM fungi, tree species (such as *N. orientalis*) and Hg was the subject of this study because of the possibility of the beneficial effect of mycorrhizae in improving the resistance of plants against Hg toxicity. The study was carried out to determine the resistance to Hg stress in *N. orientalis* seedlings inoculated with AM fungi grown on artificial Hg-polluted river sands media in pot experiment. Such knowledge would help clarify the potential of tree species (*N. orientalis*) and AM fungi as phytoremediation agents of Hg-polluted soils.

2. Materials and Methods

2.1. Plant Culture in River Sands at Different Rates of Hg

Eleven-months old seedlings of non-mycorrhizal and mycorrhizal *N. orientalis* were obtained from the nursery. Each plant was grown in a PVC pot (10 cm in diameter and 30 cm in height), containing 5 kg coarse river sands (1-2 mm) as substrate. Mycorrhizal inoculum (25 g) (Laboratory of Forest Biotechnology, Research Center for Biological Resources and Biotechnology, Bogor Agricultural University collection) was inoculated to mycorrhizal seedlings for second inoculation and sterilized mycorrhizal inoculum (25 g) and its filtrate (10 mL each pot) was applied to non-mycorrhizal seedlings. All seedlings were maintained by adding the nutrient solution for 8 weeks. The composition of the nutrient solution was as follows (mmol L⁻¹) [21]: Ca(NO₃)₂ 1.5; KNO₃ 4.0; KH₂PO₄ 1.5 and MgSO₄ 1.0. Micronutrients were supplied (μmol L⁻¹): Fe-EDDHA 36; MnSO₄·H₂O 33; ZnSO₄·7H₂O 1.6; CuSO₄·5H₂O 1.6; H₃BO₃ 46 and (NH₄)₆Mo₇O₂₄·4H₂O 0.1. The pH of nutrient solution

ranged for 5.5 to 6.0. A factorial experiment with completely randomized design with three replicates for each treatment was used. Hg treatments were 0, 375 and 750 μM, supplied as HgCl₂ salt and applied to *N. orientalis* seedlings, either with or without AM fungi inoculation treatments. The experiment was carried out in screen house of Forest Microbiology Laboratory, Research Center of Rehabilitation and Forest Conservation, Bogor, under the following conditions: 28°C-33°C temperature and 80% - 95% humidity.

2.2. Harvesting

Plants were harvested after 30 days to Hg exposure and divided into roots, stems and leaves. All plant material was thoroughly washed with tap water followed by a subsequent rinse in 20 mM EDTA solution for 1 minute and then in deionized water for 2 minutes. Total fresh weight of each tissue was determined, then a representative plants were oven-dried to constant weight at 70°C for 3 days prior to preparation for measuring dry weights and nutrients analysis, and at 50°C before preparation for Hg analysis. The rest of the material plants was frozen in liquid N₂ and stored at -20°C before chlorophyll and malondialdehyde (MDA) concentration analyzing. Water content was determined based on the difference of fresh weight and dry weight.

2.3. Analytical Determination

Dried plant sample was acid digested using 25 mL of deionized water, 3.5 mL of concentrated HNO₃ and 0.5 mL of HClO₄, added to 0.5 g dry weight (DW) in a test tube. The digested solution was analyzed for mercury concentration using inductively coupled plasma-optical emission spectrometry (ICP-OES, Spectro Genesis) excitation, and calibration was performed by using standard Hg solution [22]. Total Hg and nutrient (P, Ca and Mg) concentration were determined by ICP-OES. Chlorophylls was extracted and estimated according to Arnon in [23]. Lipid peroxidation in plant tissues was based on an estimate of malondialdehyde (MDA) concentration, as described by Heath and Packer in [12]. Mycorrhizal colonization was determined following [24].

2.4. Calculation and Statistical Analysis

Some variables were calculated to study the resistance to mercury stress of *N. orientalis* seedlings [7, 25]:

$$\text{Hg uptake (nmol Hg g}^{-1} \text{ DW)} = \frac{\text{nmol Hg plant}^{-1}}{\text{g DW}}$$

where DW is the entire-plant dry weight.

$$\text{Hg translocation (nmol Hg g}^{-1} \text{ DW)} = \frac{\text{nmol Hg leaves}^{-1}}{\text{g DW}}$$

where DW is the entire-plant dry weight.

Concerning uptake and translocation, the same procedure

was used for P, Ca, and Mg [25]. Tolerance index (TI) of mycorrhizal and non-mycorrhizal seedlings to Hg treatments were determined based on roots dry weight [26], as:

$$TI (\%) = \frac{\text{DW of roots at Hg treated}}{\text{DW of roots at non Hg treated of the same treatments}} \times 100$$

A statistical analysis for means comparison was carried out using ANOVA and least significant difference (LSD) test with CoStat 6.400.

3. Results and Discussions

3.1. Mercury Accumulation by *N. Orientalis* Seedlings

Hg accumulation in roots of *N. orientalis* seedlings was significantly increased consistently with increasing of Hg rates (Table 1), either within non-mycorrhizal or mycorrhizal seedlings. Hg concentration in the roots was 53- to 1,633-fold and Hg content in the roots was 45- to 1,513-fold higher than the control (without Hg treatment). In line with this, Hg accumulation in roots was 4- to 10-fold the concentration found in shoots of several plant species such as *B. chinensis* [7], *Brassica napus* [27] and *Zea mays* [28].

However, at the 750 μM of Hg treatment, Hg accumulation in roots of mycorrhizal seedlings was significantly decreased by 87% of Hg concentration and 84% of Hg content when compared to control (non-mycorrhizal

plants). This result shows that at the highest concentration of Hg, the AM fungi could limit Hg store in roots. This is in agreement with [20] result that mycorrhizal inoculation significantly decreased Hg concentration in maize roots with Hg at the rates of 2.0 and 4.0 mg kg^{-1} . Hyphae of AM fungi, which contain free amino, hydroxyl, carboxyl, and other groups [16], colonize outside and inside the roots. Outside the roots, the hyphae and root surface could adsorb Hg so that Hg translocation into roots could be inhibited, and inside the roots, it change cell wall components of plant, hence possibly enhancing the sequestration of Hg [20]. In line with this, buffering heavy metal-stress had been assigned, at least partly, to selective immobilization of heavy metals in those root tissues that contain fungal structures [29] or to the high metal sorption capacity of the extraradical mycelium of AMF [30].

This finding supports results from numerous studies reporting that AM fungi often protect plants against high accumulation of toxic elements in the shoots, as it was reported for Cu [17], Al [31], Cd [17,32], Zn [33], Pb [17,34], U [35] and As [36]. In addition, glomalin, an insoluble glycoprotein which is contained in hyphae and spores of AM fungi, had a high binding capacity for Cu, Cd and Pb [17], hence it could act as a biostabilizer for the remediation of polluted soils. Glomalin could be considered for Hg sequestration in hyphae and spores of AM fungi as well. This presumption need to be investigated in further research.

Table 1. Hg concentration and Hg content in roots and leaves of *N. orientalis* seedlings grown for 30 days in river sands treated with different Hg concentrations and mycorrhizal inoculation.

Hg (μM)	Arbuscular mycorrhizal inoculation

Significant differences among Hg treatments are indicated by different letter (mean $\pm$ SE, n = 3; LSD's test, $p < 0.05$). nd = not detected

The very small of Hg concentration and content in leaves of *N. orientalis*, either in non-mycorrhizal or mycorrhizal seedlings, showed that Hg accumulation in leaves was inhibited (Table 1). However, there is a tendency that Hg concentration and Hg content were higher in leaves of mycorrhizal seedlings than non-mycorrhizal seedlings when the highest Hg was applied. This result indicates that AM fungi play an important role in accumulation of Hg in plant.

Hg uptake by seedlings and Hg translocation of root to shoot were very limited as well (Table 2). These results are in agreement with previous studies [37], that roots were the

main organs for Hg retention in *Halimione portulacoides*. Various studies have indicated that only a very small amount of Hg is translocated to plant shoot after root uptake and Hg in shoots mainly comes from the uptake of air Hg [7,11,38,39]. Metal retention in roots can be a strategy for protecting the more sensitive aerial parts from the deleterious effects induced by metal stress [40] and it has been reported that in most plant species, metal ions are preferably retained in root tissues and only small portions are translocated to leaves. Hg accumulated by mycorrhizal and non-mycorrhizal seedlings was mostly distributed in root tissues, suggesting that an exclusion strategy for Hg

tolerance widely exists in them. In addition, evaporation of Hg from soil/growth medium to atmosphere was promoted by mycorrhizal treatment [20].

3.2. Effects on Plant growth and Nutrient Distribution

Early and direct phytotoxic symptoms of heavy metals, such as Hg, are the reduction in cell proliferation and inhibition of growth, and are frequently used as a phytotoxic index, followed by analyzing several physiological parameters [41,42]. Hg treatment caused no significant differences in biomass (fresh and dry weight of

plants) and water content in non-mycorrhizal and mycorrhizal seedlings of *N. orientalis*, when compared to the control (without Hg treatment) (data not shown). It means that there was not a reduction of plant growth caused by Hg application up to 750 μM during 30 days of Hg exposure. In line with observations on growth, the non-mycorrhizal and mycorrhizal seedlings have a high tolerance to Hg (>70%) (Table 3). There were not toxicity symptoms in *N. orientalis* seedlings grown for 30 days after Hg exposure.

Table 2. Hg uptake and translocation in *N. orientalis* seedlings grown for 30 days in river sands treated with different Hg concentrations and mycorrhizal inoculation.

Hg (μM)	Arbuscular mycorrhizal inoculation			
	Without	With	Without	With

0	nd	nd	nd	nd
375	nd	nd	nd	nd
750	0.016 ± 0.006	0.040 ± 0.005	0.003 ± 0.002	0.013 ± 0.001

* Mean $\pm$ SE, n = 3; nd = not detected

Roots of inoculated plants were extensively colonized by AM fungi, while non-inoculated controls remained non-mycorrhizal (Table 3). The percentage of AM colonization was slightly reduced in the presence of Hg in river sands substrate. This result indicates that the concentrations of Hg in the substrate was slightly harm to

AM fungi. Reference [26] reported that sensitivity of AM symbionts to heavy metal contaminated soil expressed as a reduction in root colonization. In contrast, [20] reported that addition of Hg in soil did not significantly influence root colonization rate in maize.

Table 3. Tolerance index and AM colonization of *N. orientalis* seedlings grown for 30 days in river sands treated with different Hg concentrations and mycorrhizal inoculation.

Hg (μM)	Arbuscular mycorrhizal inoculation			
	Without	With	Without	With
	Tolerance index* (%)		AM colonization (%)	
0	100.0	100.0	0	78.1
375	89.1	71.1	0	66.0
750	95.9	77.2	0	58.5

* The tolerance index was based on root dry weight

Figure 1. P translocation in seedlings of *N. orientalis* treated with arbuscular mycorrhizal inoculation (a) (mean $\pm$ SE, n = 9) and different Hg concentration (b) (mean $\pm$ SE, n = 6). Significant difference among Hg treatments and AM inoculation are indicated by different letter (LSD's test, $p < 0.05$).

Another interesting result in Table 3 was that the presence of AM fungi could increased 8.6% of tolerance index of seedlings treated with 750 μM Hg compared with seedlings treated with 375 μM . This result emphasizes that AM fungi could be potentially effective in protecting seedlings exposed to high levels of Hg concentration. The AM fungi

ability to alleviate heavy metals stress of plants grown in heavy metal contaminated soil was previously proved by [31,43]. The highly AM colonization in seedlings treated with Hg indicated that AM fungi still function in Hg substrate.

In addition, AM fungi still affected uptake and

translocation of nutrients (P, Ca and Mg) as well. P translocation was increased significantly in seedlings treated with AM inoculation as single factor (Fig. 1A). AM fungi increased P translocation in plant 35% higher than control (without AM inoculation). Previous research reported that AM fungus (*Glomus mosseae*) increased the absorption of P for plant growth on red clover (*Trifolium pratense*) treated with different Zn rate levels [44].

On the other hand, P translocation to leaf was significantly increased 40% in seedlings treated with the highest of Hg application (Fig. 1B), higher than control (without Hg). This result indicates that increasing P translocation to leaf was induced by the highest of Hg application. In addition, AM inoculation caused significantly increased in Ca and Mg uptake and translocation of *N. orientalis* treated with the

highest of Hg application (Table 4). Nutrient uptake and translocation to shoot depend on water movement in xylem, and a reduction of water absorption could also disturb micronutrients distribution [5]. Water content in each tissue of seedlings did not decrease during Hg exposure, indirectly, showed that water movement within the seedlings was not disturbed by Hg application. Therefore, nutrients distribution (especially P, Ca and Mg) in *N. orientalis* seedlings were not inhibited. In reference [5] stated that the increase of some nutrients in response to trace toxic elements could be a strategy to avoid toxicity in plants, although a contribution of concentration effects after Hg application cannot be ruled out. The role of AM fungi in the increase of plant nutrients could also be an important strategy to enhance the resistance to Hg stress.

Table 4. Ca and Mg uptake and translocation in *N. orientalis* seedlings grown for 30 days in river sands treated with different Hg concentrations and mycorrhizal inoculation.

Hg (μM)	Arbuscular mycorrhizal inoculation

0	16.7 $\pm$ 1.3 b	16.2 $\pm$ 0.6 b	78.0 $\pm$ 7.1 b	79.4 $\pm$ 8.1 b
375	16.5 $\pm$ 1.5 b	17.7 $\pm$ 0.2 b	85.1 $\pm$ 3.0 b	97.2 $\pm$ 3.0 b
750	15.9 $\pm$ 0.4 b	24.1 $\pm$ 1.2 a	82.7 $\pm$ 7.6 b	131.9 $\pm$ 10.3 a

Significant differences among Hg treatments are indicated by different letter (mean $\pm$ SE, n = 3; LSD's test, p<0.05)

3.3. Effect of Mercury and Arbuscular Mycorrhizal Fungi on Chlorophyll and Lipid Peroxidation

Chlorophylls and MDA have been used as biomarkers, which can be used in the early diagnosis of metal toxicity [45]. Mercury inhibits enzymes involved in chlorophyll synthesis [46] and consequently, reduced chlorophyll levels have been observed [4]. In this research, chlorophyll (a, b and total) concentration in *N. orientalis* seedlings remained unchanged during exposure to Hg treatment (data not shown). This means that the process of photosynthesis was not impaired by Hg up to 750 μM on river sands media. This result was contrasts with research as in [5] which chlorophyll a concentration in *R. induratus* and *M. vulgare* were decreased significantly, while chlorophyll b levels remained unchanged by 5, 10, and 50 μM Hg rates when cultivated after Hg exposure for 2 months. There were not toxicity symptoms in leaves of *N. orientalis* seedlings during 30 days of Hg exposure. Enhancement of chlorophyll b concentration was observed in *N. orientalis* seedlings inoculated with AM fungi (Fig. 2). AM fungi resulted in significant increased chlorophyll b concentration by 15% when compared to the control (non-mycorrhiza). Increased chlorophyll b concentration could increase the accessory

pigment that collects the energy to pass on to chlorophyll a.

Figure 2. Chlorophyll b concentration of seedlings inoculated with arbuscular mycorrhiza (mean $\pm$ SE, n = 9). Significant difference for each AM inoculation treatments are indicated by different letter (LSD's test, p<0.05).

Exposure of plants to non-redox-reactive heavy metal, such as Hg, resulted in oxidative stress as indicated by lipid peroxidation, H₂O₂ accumulation, and an oxidative burst [47]. Lipid peroxidation reflected the toxic effects of Hg on the cell membrane in tissues [7]. In this research, only

malondialdehyde (MDA) was measured as a variable of lipid peroxidation. Roots of *N. orientalis* seedlings did not show any significantly increased in lipid peroxidation when Hg treatment is applied as a single factor (data not shown). It showed that oxidative stress was not observed in roots with Hg application, even though Hg was accumulated in roots. On the other hand, MDA concentration in roots of mycorrhizal seedlings was significantly decreased by 76% when it was compared to the control (non-mycorrhizal) (Fig. 3). It means that lipid peroxidation was reduced by AM fungi, consequently, the oxidative stress in roots could be minimized.

Figure 3. MDA concentration in roots of seedlings inoculated with arbuscular mycorrhiza (mean $\pm$ SE, $n = 9$). Significant difference among AM inoculation treatments are indicated by different letter (LSD's test, $p < 0.05$).

In contrast to MDA concentration in roots, MDA concentration in leaves of *N. orientalis* seedlings was significantly affected by combined effects of Hg application and AM inoculation (Fig. 4). At the 0 μ M and 375 μ M Hg concentration, MDA concentration within leaves of mycorrhizal seedlings were higher than within non-mycorrhizal seedlings, but they did not differ significantly with the MDA concentration in leaves of mycorrhizal seedlings at the 750 μ M Hg concentration.

Figure 4. MDA concentration in leaves of *N. orientalis* seedlings with different Hg concentration (mean $\pm$ SE, $n = 3$). Significant difference among Hg treatments are indicated by different letter (LSD's test, $p < 0.05$).

It indicates that the inoculation of AM fungi to *N. orientalis* seedlings minimized the increased of lipid peroxidation when Hg concentration was increased. However, in non-mycorrhizal seedlings, MDA concentration in leaves increased with increased Hg concentration. At the highest concentration of Hg, MDA concentration in leaves of non-mycorrhizal plants was increased significantly by 116% compared to the mycorrhizal plants. In line with this, MDA levels in tomato plant tissues increase in response to Hg [4] as a consequence of higher lipid peroxidation. Although there was the significant increase of MDA concentration, it did not cause toxicity in non-mycorrhizal seedlings. It reveal that *N. orientalis* is included Hg tolerance species.

4. Conclusions

A major part of Hg accumulated by *N. orientalis* seedlings was in root. Translocation of Hg to the aerial part of the plant (leaves) was limited so that the contents were relatively constant even though the Hg concentration in the growth media was higher. Mycorrhizal symbiosis showed a significant effect of the resistance to Hg stress of *N. orientalis* plants grown in Hg treated and non-treated Hg media. *N. orientalis* seedlings have a high tolerance to Hg exposure (>70%). The recently results indicate the potential of *N. orientalis* and AM fungi to be used in the long-term land reclamation strategy, including land use purposes beneficial in areas Hg-polluted.
