Abstract: The study was conducted with the objective to identify adaptable, high biomass yield, leaf to stem ratio and good quality yield of Alfalfa cultivars at Bore Agricultural research center. Eight Alfalfa cultivars; Hunter river, Magna-801-FG, Pioneer (1995) DZF-406, Segule1396 (408), Peruvian DZF (406), F-G-9-09, F-L-L-77-(406) and Hunter river (4010) were tested in RCBD with three replications. Plant height was significantly ($P<0.05$) higher for Hairy (1995) DZF-406 cultivar (83 cm) while lower for Magna-801-FG. Disease resistance was significantly differ ($P<0.05$) among cultivars. Segule (1396)-408 cultivars were highly resistant to diseases compared to others. Leaf to stem ratio, biomass yield and seed yield were not show significant ($P>0.05$) different among treatments. Chemical compositions of NDF, ADL and CP were significantly ($P<0.05$) different among treatments. The superior ADL was obtained from Segule (1396)-408 cultivar (32.5%) while, low was obtained from F-L-L-77 (406) cultivar. The superior NDF was obtained from Poineer (1995) DZF-406 cultivar (70.7%) whereas; the low was from Peruvien- DZF- 406 cultivar (45.9%). The CP yield showed significant ($P<0.05$) difference among cultivars. Magna- 801-FG cultivar had the superior (26.3%) CP while, Segule (1396)-408 cultivar (11.3%) had the inferior CP content. Cultivar F-G-9-09 was produce superior in DM (91.8%) and less in ADL (9.3%) while Segule 1396 (1396)-408 cultivar produce (91.3%) DM and lower in TASH (10.8%). superior OM was obtained from Segule 1396 (408) cultivar (80.4%) compared to others. Based on its yield, plant height, biomass yield and chemical compositions, good DM and OM Peruvien-DZF- 406, F-L-L-77 (406,) Segule-1396 (408) and F-G-9-09 is recommended for further promotion in the highland and midland of Guji and similar agro-ecologies.

Keywords: Medicago, Sativa, Adola, Cultivar

1. Introduction

Alfalfa (*Medicago sativa* L.) is often recognized as one of the most important perennial forage legumes worldwide and is widely known as the “queen of the forages” due to its ability to consistently produce high forage yield and forage quality and adaptability to different climatic conditions [1, 2]. Alfalfa is a drought tolerant forage crop because it has a deep root system that reaches down to 4 m and to 7-9 m in well drained soils. The plant survive long periods of water stress by impeding its vegetative growth [3] and accessing water from deep layers through its long root system [4]. The optimum growing air and soil temperatures for alfalfa are 27°C and 12°C respectively, but it is tolerant of air

temperatures above and below 27°C [5].

This forage legume is also known as an effective source of biological nitrogen fixation, an energy-efficient crop to grow and an important source of protein yield. The optimum soil pH range for alfalfa is 6.5 to 7.5 and tolerates relative salinity. Alfalfa grows best on well-drained, deep soils but it thrives on sandy soils with adequate moisture and fertility [6]. Alfalfa does not grow well on soils where root growth is limited such as shallow hardpans, high water tables, bedrock or acidic sub soils [7].

Poorly drained or waterlogged soils are strongly discouraged for alfalfa because root and crown diseases reduce stand longevity under these conditions. The crop needs very frequent irrigation during its early growth period

at an interval of about one week but once the plants are established, subsequent irrigations are provided at an interval of 10-15 days during dry season. Alfalfa is one of the few cultivated forage crops that can produce high level of biomass with minimum inputs. Low quality crop residues need nitrogen supplementation, often provided by forage legumes to become productive diets [8].

Climate, cultivation practices, feed technologies and genetic variations are the main factors affecting the nutritional value of feed for livestock. Forage legumes contribute significantly to livestock production in crop livestock systems. Legume forages generally lead to higher intakes and animal production than grass silages of comparable digestibility [9]. Alfalfa nutritive value is identified with protein content which depends on the share of leaves in dry matter yield which in turn is positively correlated with protein content. The proportion of leaves and stems in alfalfa hay can vary greatly, depending on maturity at harvest, cultivars, handling and rain damage [10]. Protein content in alfalfa dry matter varies from 18 to 25% depending on the growth stage, cultivar difference and other factors. Alfalfa is one of the most important forage legumes of the world as major source of protein for livestock and it is a basic component in rations for all classes of domestic animals [11].

Where alfalfa can easily be grown, it is regarded as key forage for high-producing ruminants because of its richness in protein, palatability, high calcium and vitamin content. In many cases animals feeding on alfalfa do not require supplements. [12] noted that because of its very high feed value, alfalfa should be used as a supplement for crop residues and natural hay in mixture of 30 percent alfalfa and 70 percent other roughages. Alfalfa produces more protein per hectare than other legume and grasses; therefore, it is widely used for hay production and as pasture for livestock, especially to ruminants [13]. Ruminants fed on alfalfa have higher nutrient intake and digestibility than when fed on other forage legumes and grasses [14]. To improve availability of livestock feed in terms of quantity and quality, it is better to cultivate alfalfa forage that have better biomass yield and nutritional quality. Therefore, the objective of the present study was to evaluate the adaptability potential Good biomass yield, leaf to stem ratio and nutritional quality of alfalfa cultivars grown at high land and mid land parts of Guji zone.

2. Materials and Methods

2.1. Description of the Study Area

The experiment was carried out at Songo baricha on station and Adola sub-site of Bore Agricultural Research Center. Bore district is located at 385 km to the south of Oromia from Finfinne and 220 km from the Guji Zone capital city (Negele) with geographical location of 55°23' to 62°52' N latitudes and 38°25'51" to 38°56'21" E longitudes, South-eastern Oromia. The annual rain fall is about 1400-1800mm and the annual temperatures of the district ranged from 10.1 to 20°C. The major soil types of the site are mostly black soil. Bore Agricultural Research station is located at 7

km from Bore district which is geographically located at 62°43'7" N latitude and 38°34'76" E longitudes. The research station represents highlands of Guji Zone with an altitude of 2736 m. a. s. l. receiving high rainfall characterized by bimodal distribution. The first rainy season extends from April to October and the second season starts late November and ends at the beginning of March. Adola district is located at distance of 470 km from Addis Ababa and 120 km from the Zonal capital city, Negele Borena. The areas are a mixed farming and semi-nomadic economic activity takes place, which is the major livelihood of the local peoples. The District is situated at 5°44'10" - 6°12'38" N and 38°45'10" - 3°12'37" E. The District is characterized by highland (11%), midland (29%) and lowland (60%). The major soil types of the district are nitosols (red basaltic soils) and orthic acrosols [15].

2.2. Experimental Treatments and Design

The experiment was conducted using eight Alfalfa cultivars Hunter river, Magna-801-FG, Pioneer (1995) DZF-406, Segule1396 (408), Peruvian DZF (406), F-G-9-09, F-L-L-77-406 and Hunter river (4010). The experiment was conducted in randomized complete block design (RCBD) with three replications. Seeds were sown in rows spaced 20 cm and 1 m, 1.5 m between plot and block respectively on plot size of 2 m x 2 m (4 m²). Seed & fertilizer was applied and other agronomic crop protection practices were adopted uniformly as per recommendation for production.

2.3. Methods of Data Collections

All relevant data like plant height, Biomass yield, seed yield, leaf to stem ratio and resistance to disease and insect were carefully recorded.

2.4. Chemical Analysis

For forage quality analysis, chopped herbage of the three replications were pooled into one and properly homogenized and one representative subsample was taken for each cultivar. The DM and ash contents were determined by oven drying at 105°C overnight and by igniting in a muffle furnace at 500°C for 6 hours, respectively. Nitrogen (N) content was determined by Kjeldahl method and CP was calculated as N x 6.25 [16]. The neutral detergent fiber (NDF), acid detergent fiber (ADF) and acid detergent lignin (ADL) fractions were analyzed according to [17].

2.5. Statistical Analysis

All collected data were analyzed using general linear model procedure SAS [18]. version 9.1. Means were separated with least significant difference (LSD) at 5% significant level. The statistical model for the analysis data was: $Y_{ijk} = \mu + A_j + B_i + e_{ijk}$

Where; Y_{ijk} = response of variable under examination, μ = overall mean, A_j = the jth factor effect of treatment, B_i = the ith factor effect of block/ replication, e_{ijk} = the random error.

3. Results and Discussions

3.1. Yield and Yield Related Components

The experiment was conducted on eight improved *Alfalfa* cultivars to select the highest yield and best performing in all agronomic traits and good quality compositions. Combined mean values of agronomic characters, mean values of agronomic traits and yield components of *Alfalfa* cultivars on different locations and combined mean values of chemical compositions are presented in Table 1, Table 2 and Table 3 respectively.

Plant Height at Forage Harvesting Stage

For plant height determination, mean height of five randomly selected plants were recorded for each plot of the trial. Plant height was significantly different ($P < 0.05$) among cultivars at forage harvesting stages Table 1. Plant height was significantly higher for Hairy (1995) DZF-406 cultivar (83 cm) and medium for F-L-L-77 (406) cultivar (82.9 cm) whereas lower for Magna-801-FG cultivar (63.8 cm). The result of this study agreed with that of [19] where they reported significant variation for *Alfalfa* cultivars.

Disease Resistance

Disease resistance was significantly different ($P < 0.05$) among cultivars at different growth stages of the forages Table 1. From eight *Alfalfa* adapted at Bore Agricultural research center, four cultivars *Hunter River* (4010), *Pioneer* (1995) DZF-406, *Hunter River* and F-L-L-77 (406) were highly attacked by diseases while *Magna- 801-FG*, *Peruvien-DZF- 406*, F-G-9-09 and *Segule* (1396)-408 cultivars were resistant to diseases compared to the other cultivars observed in the study areas over two consecutive years.

Mean Fractions of Leaf to Steam Ratio

Leaf to stem ratio was determined by separately harvesting a central section of two adjacent middle rows with a sampling area of 0.25 m² (0.5 m length x 0.5 m width) and by partitioning the harvested biomass into leaf and stem fractions. Leaf to stem ratio was not significantly different ($P > 0.05$) among *alfalfa* cultivars at forage harvesting stage. Leaf to stem ratio was superior for *Hunter river-4010* cultivar (0.71) followed by *Peruvien- DZF-406* cultivar (0.69) and the lower was obtained from *Pioneer (1995) DZF-406 cultivar* (0.54). This is agreed with the results of [20, 21]. The non-significant cultivars differences in leaf to stem ratio at forage harvesting stage observed in the present study is in disagreement with other reports [22-24, 21], but happens at the same time with other research findings [25, 19, 26].

Mean Biomass yield of Cultivars

Fresh weight of the cut biomass was recorded just after mowing using field balance. Then, sub-samples of 300g was taken and dried in air draft oven at 65°C for 72 hours to determine herbage dry matter yield (DMY). The combined mean biomass yield were not show significant ($P > 0.05$) different among treatments. The highest mean value of biomass yield was obtained from *Segule-1396-(408)* cultivar (8.2 t/ha) followed by F-L-L-77 (406) cultivar (8.07 t/ha). The lowest biomass yield was obtained from *Hunter river (4010)* cultivar (7.13 t/ha).

Combined Mean Seed Yield

Combined mean seed yield were not show significant ($P > 0.05$) different among treatments. The superior seed yield was obtained from *Segule-1396 (408)* cultivar (0.083 qt/ha) and the lower seed yield was obtained from *Hunter river (4010)*, *Hunter river*, F-L-L-77 (406) and *Magna- 801-FG* cultivars respectively.

Table 1. Combined mean values of different agronomic traits and yield related components of *Alfalfa* cultivars from two locations Adola sub-site and Songo on station.

| Cultivars | PH (cm) | D _s | LSR | SY qt ⁻¹ | fBMYt ⁻¹ |
|------------------------|-------------------|---------------------|------|---------------------|---------------------|
| F-L-L-77 (406) | 82.9 ^a | 1.42 ^{abc} | 0.63 | 0.08 | 8.07 |

| CV | 17.1 | 140 | 33.2 | 21.18 | 28.9 |
| LSD (5%) | * | * | NS | NS | NS |

^{a,b,c} Mean in a column within the same category having different superscripts differ significantly ($p < 0.05$) PH (cm)=plant height in centimeter, D_s=Disease resistance, LSR=leaf to stem ratio, SYqt⁻¹=seed yield cunatal per hectare, fBMYt⁻¹= fresh biomass yield tone per hectare, CV=Coefficient of variation, LSD=Least significant difference, *= significantly different, NS= None significant different.

Yield and yield Related of Alfalfa Cultivars from Different Locations

Mean value of agronomic and yield parameters of *alfalfa* cultivars are show in Table 2. The analyzed result show that plant height and disease were significantly ($P < 0.05$) different among treatments. *Alfalfa* cultivars were more attacked by diseases at Songo on station than at Adola sub-site. Highly

attacked cultivar by diseases was *Hunter river cultivar* (2.5) at Songo on station where as, *Magna-801-FG* cultivar (2) were highly diseased at Adola sub-site. *Segule-1396 (408)* cultivar was resistant to disease at both locations and *Magna-801-FG* cultivar at Songo on station. The rest cultivars were comparable with each others at both locations.

The long plant height was measured from F-L-L-77 (406)

cultivar (99.22 cm) at Adola sub-site whereas; Segule-1396 (408) cultivar (76.05 cm) was the long plant height at Songo on station. On the other hand the short plant height was obtained from *Magna -801-FG* (69.5 cm) cultivar at Adola

sub-site and Hunter River (4010) cultivar (49 cm) at Songo on station compared to the other cultivars.

Leaf to steam ratio, Biomass yield and seed yield were not show significant ($P>0.05$) different among treatments.

Table 2. Mean value of agronomic traits and yield components of Alfalfa cultivars on different locations.

| Cultivars | Locations | | | | | | | | | |

3.2. Chemical Composition

From tested alfalfa cultivars, all the traits showed non-significant ($P>0.05$) difference except NDF, ADL and CP Table 3. Alfalfa *F-G-9-09* cultivar was produce superior in DM (91.8%) and less in ADL (9.3%) while Segule 1396 (1396) - 408 cultivar produce (91.3%) DM and lower in TASH (10.8%). The higher result of current study was (91.8%) dry matter percentage which was higher than the result reported. The highest OM was obtained from Segule 1396 (408) (80.4%) cultivar, flowed by *F-G-9-09* (80.1%) cultivar. The superior ADL was obtained from *Segule (1396)-408* cultivar (32.5%), followed by Hunter River *Poineer (1995) DZF-406* cultivar (20.5%) whereas the last was obtained from *F-L-L-77 (406)* cultivar. The ADL content showed variability ($P<0.05$) difference among the tested alfalfa cultivars, this is dis-agreed with result reported by [19, 21].

The superior NDF was obtained from *Poineer (1995) DZF-406* cultivar (70.7%), followed by *Hanter River* cultivar (64.8%) where as the least was from *Peruvien- DZF- 406 cultivar (45.9%)*. This result is agreement with the result reported by [19] NDF contents of alfalfa cultivars but, disagreement to the result [21] reported non-significant differences for NDF contents of alfalfa cultivars. The current results revealed that the highest NDF contents recorded for *Poineer (1995) DZF-406*, indicating low quality alfalfa cultivar when compared with others [19].

The CP yield showed significant ($P<0.05$) difference among the tested cultivars. The result revealed that *Magna-801-FG* cultivar had the highest (26.3%) CP followed by *Hanter River (4010) cultivar (24.6%)* while *Segule (1396)-408 cultivar (11.3%)* had the lowest CP content. This result is des- agreed with the result reported by [19] for the same cultivar evaluated under supplementary irrigation.

Table 3. Combined mean chemical composition of alfalfa cultivar from Adola sub-site and Songo on station.

| Cultivars | DM | TASH | OM | NDF | ADF | ADL | CP |
|-------------------------------|-------|-------|-------|---------------------|-------|--------------------|--------------------|
| <i>F-L-L-77 (406)</i> | 89.4 | 13.7 | 75.7 | 46.3 ^c | 43.5 | 11.6 ^b | 22.9 ^{ab} |
| <i>Magna- 801-FG</i> | 90.8 | 12.5 | 78.3 | 57 ^{abc} | 43.75 | 21.6 ^{ab} | 26.3 ^a |
| <i>Peruvien- DZF- 406</i> | 88.17 | 13.3 | 74.79 | 45.9 ^c | 40.7 | 9.47 ^b | 17.4 ^{bc} |
| <i>F-G-9-09</i> | 91.8 | 11.6 | 80.1 | 55.1 ^{bc} | 37.6 | 9.3 ^b | 22.5 ^{ab} |
| <i>Poineer (1995) DZF-406</i> | 90.7 | 12.4 | 78.34 | 70.7 ^a | 40.9 | 20.3 ^{ab} | 22.2 ^a |
| <i>Segule (1396)-408</i> | 91.3 | 10.8 | 80.4 | 58a ^{bc} | 40.8 | 32.5 ^a | 11.3 ^c |
| <i>Hanter River (4010)</i> | 89.6 | 12.9 | 76.72 | 58.4 ^{abc} | 37.4 | 13.3 ^b | 24.6 ^{ab} |
| <i>Hanter River</i> | 90.3 | 12.3 | 78 | 64.8 ^{ab} | 44.7 | 15.8 ^b | 23.4 ^{ab} |
| Mean | 90.28 | 12.46 | 77.8 | 57 | 41.2 | 16.7 | 21.3 |
| CV | 2 | 14.79 | 3.8 | 9.5 | 13.1 | 31.3 | 15.6 |
| LSD (5%) | NS | NS | NS | * | NS | * | * |

^{a,b,c} Mean in a column within the same category having different superscripts differ significantly ($p<0.05$) DM=dry matter, TASH=total ash, OM=organic matter, NDF=neutral detergent fiber, ADF=acid detergent fiber, ADL=acid detergent lignin, CP= crude protein, CV=Coefficient of variation, LSD= Least significant difference, *= significantly different, NS= None significant different.

4. Conclusions and Recommendations

The result implies that *Peruvien- DZF- 406, F-L-L-77 (406)*, Segule-1396 (408) and F-G-9-09 cultivars were well adapted and being productive regarding the plant height, biomass yield and leaf to stem ratio which, is hopeful to fill the gap of low quality and quantity ruminant feed supply of the community. The current study indicated that Segule-1396 (408) cultivar was resistant to disease at both study area. Regarding the nutritional values (chemical composition) were promising particularly the dry matter (DM) and Organic Matter (OM) content in *Peruvien- DZF- 406, F-L-L-77 (406)*, Segule-1396 (408) and F-G-9-09. Thus, it could be possible to conclude that Alfalfa cultivars especially Segule-1396 (408) and F-G-9-09 used as a protein supplement for highland and midland of Guji, which were suffering from poor quality roughage and low protein and digestible crop residues which were the major livestock feed sources particularly in Guji. Based on its adaptability, plant height, biomass yield and chemical compositions, good DM and OM *Peruvien- DZF- 406, F-L-L-77 (406)*, Segule-1396 (408) and F-G-9-09 is recommended for further promotion in the highland and midland of Guji and similar agro-ecologies.

Acknowledgements

The authors are grateful to the Oromia Agricultural Research Institute (IQOO) for financial support to implement the study. The animal nutrition laboratory workers of Haramaya University and Debre zeyit agricultural research center were also acknowledged for their support in the chemical analysis of the feed samples.
